OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION—1917-1918

GENERAL OFFICERS

President—Charles H Mayo	Rochester, Minn
President-Elect—Arthur Dean Bevan	Chicago
First Vice President—Edward H Bradford	Boston
Second Vice President—John McMullen	U S Public Health Service
Third Vice President—Lawrence Litchfield	Pittsburgh
Fourth Vice President—Holman Taylor	Fort Worth, Texas
Secretary—Alexander R Craig	535 N Dearborn St, Chicago
Treasurer—William Allen Pusey	Chicago
Chairman, House of Delegates—Hubert Work	Pueblo, Colo
Vice Chairman, House of Delegates—Dwight H Murray	Syracuse N Y
Editor and General Manager—George H Simmons	535 N Dearborn St, Chicago

BOARD OF TRUSTEES

M L Harris, Secretary	Chicago, 1918
Wendell C Phillips	New York, 1918
Thomas McDavitt, Chairman	St Paul, 1918
A R Mitchell	Lincoln, Neb, 1919
E J McKnight	Hartford, Conn, 1919
Oscar Dowling	Shreveport, La, 1919
Philip Marvel	Atlantic City, 1920
W T Sarles	Sparta, Wis, 1920
H Bert Ellis	Los Angeles, 1920

JUDICIAL COUNCIL

A B Cooke	Los Angeles, 1918
Alexander Lambert, Chairman	New York, 1919
James E Moore	Minneapolis, 1920
H A Black	Pueblo, Colo, 1921
Randolph Winslow	Baltimore, 1922
Alexander R Craig, Secretary	535 N Dearborn St, Chicago

COUNCIL ON HEALTH AND PUBLIC INSTRUCTION

W S Rankin	Raleigh, N C, 1918
H M Bracken	Minneapolis, 1919
Milton Board	Louisville, Ky, 1920
Frank Billings, Chairman	Chicago, 1921
Walter B Cannon	Boston, 1922
Frederick R Green, Secretary	535 N Dearborn St, Chicago

COUNCIL ON MEDICAL EDUCATION

H D Arnold, Chairman	Boston, 1918
H Gideon Wells	Chicago, 1919
Robert C Coffey	Portland, Ore, 1920
W D Haggard	Nashville, Tenn, 1921
William Pepper	Philadelphia, 1922
N P Colwell, Secretary	535 N Dearborn St, Chicago

COUNCIL ON SCIENTIFIC ASSEMBLY

Roger S Morris	Cincinnati, 1918
George H Simmons	Chicago, 1919
J Shelton Horsley	Richmond, Va, 1920
E S Judd, Chairman	Rochester, Minn, 1921
Alexander R Craig Secretary of the Association, ex officio	

COUNCIL ON PHARMACY AND CHEMISTRY

David L Edsall	Boston, 1918
R A Hatcher	New York, 1918
A W Hewlett	San Francisco, 1918
John Howland	Baltimore, 1919
Henry Kraemer	Philadelphia, 1919
C L Alsberg	Washington, D C, 1919
G W McCoy	Washington, D C, 1920
F G Novy	Ann Arbor, Mich, 1920
George H Simmons, Chairman	Chicago, 1920
L G Rowntree	Minneapolis, 1921
Torald Sollmann	Cleveland, 1921
Lafayette B Mendell	New Haven, Conn, 1921
Reid Hunt	Boston, 1922
J H Long	Chicago, 1922
Julius Stieglitz	Chicago, 1922
W A Puckner, Secretary	535 N Dearborn St, Chicago

INDUSTRIAL MEDICINE AND SURGERY THE NEW SPECIALTY*

HARRY E. MOCK, M.D.
CHICAGO

Preventive medicine and preventive surgery within the last five years have become a very active factor in the industrial life of our country. Our modern industrial concerns have employed experts to study their expensive, complicated machines, in order to preserve their mechanism and obtain their maximum of efficiency.[1] The human machine alone was neglected.

Gradually, due to both external and internal causes, a new, humanizing influence pervaded a few of these industries, and they began to consider the welfare or betterment of the employees from various angles. It was soon apparent that this movement reacted to the welfare of the employers. The realization of this mutual benefit to employee and employer marked the birth of an entirely new economic point of view which is rapidly extending to every branch of our American industrial life.

The conservation of life by the prevention of disease and accidents among employees, the basic principle underlying all forms of industrial medicine, is the greatest influence for socialization in our country at present. And to the company surgeon of today and of the future is given the opportunity of extending medical science into this vast, unlimited field of endeavor. In the past, and in many industries at the present time, the care of those meeting with accidents has been the chief duty of the company surgeon, with very little attention paid to the protection, the health and the working ability of the individual employee. Likewise, concerns having company surgeons often fail to realize the great economic advantage at their disposal for increasing efficiency by utilizing the expert knowledge of their physicians along these lines.

Due to this ignorance on the part of so many industries and the lack of vision and enthusiasm on the part of many company surgeons, this field of medicine has been considered very narrow, and the physicians engaged therein have been insufficiently paid, resulting in a restricted growth, and have been viewed with more or less contempt by the majority of the profession. But when a company surgeon realizes that for greater efficiency an employer has the right to demand a healthful, physically and mentally normal working force, and that the employee would be, and is, justified in demanding a healthful, sanitary working place, uncontaminated by diseased fellow employees, and that business principles, as well as a spirit of humanitarianism, demands all his powers for the conservation of the life and limb of the employee, and when he attains the vision of all that this means, and brings to his work an undying enthusiasm and a knowledge sufficient to master every detail, then he becomes of unlimited value to the concern for which he works, and is remunerated accordingly. And, most gratifying to him personally, he is recognized as an equal by his fellow physicians and as an advanced student in the science of medicine.

It is apparent that the company surgeon of the future must be a very broadly trained physician. Some of the largest industries can afford to have several doctors on their staff and thus can divide the medical work into its various specialties, but even here the chief of staff must be trained thoroughly in all branches of this work. In the smaller corporations, however, the company surgeon must be a surgeon, an internist, a diagnostician, a sanitation expert and an all-round medical utility man. As he follows the growing ramifications of his work and realizes its influence on the individual employee, its influence on the industrial concern and finally its influence on the community and society in general, and sees the state being forced to assume the responsibilities that his work is making so apparent, then the company surgeon gradually awakens to the fact that he has become a sociologist as well as a physician. Armed with this broader point of view, he becomes not only a doctor for the ills of the individual, but a physician to the ills of society.

Industrial medicine and surgery is rendering a wonderful service to the great mass of workers, but it is also rendering a greater service to those physicians engaged in the work. It is molding them into specialists in the great medicosociological problems which are confronting this country more and more.

The size of the medical staff, the size and location of the doctor's office or company hospital, and the amount of work necessary to conduct a comprehensive plan of medical and surgical supervision of the health of employees must depend chiefly on the size, number of employees and the type of work of each industry. These are details which each company surgeon must work out, and which will certainly be changed with the growth of his work.

The industry with which the writer is connected has gradually extended its medical staff and equipment from a four-room office with one doctor and two nurses in 1909, to an eighteen-room office with seven doctors, twelve nurses and two dentists in 1916. The doctors spend three and one-half hours per day at this work, so rotating that there is always some one in charge of the company office. While many of our best company surgeons devote all of their time to the industries employing them, yet, as a rule, the various corporations will find that they can secure better-trained and broader physicians if they require them to give only a part of their time to this work. The situation is quite analogous to that found in our leading medical schools. The heads of departments and those associated with them give a portion of each day to teaching and clinical work, the rest of their time is given to private practice, study and investigation. Because of their clinical experience and the broadening influence of their private and public work, these men become the leaders and scholars in our profession and their influence in the community at large is much greater than it would be if they devoted their entire time, on a salary, to teaching in a medical school. Thus with a company surgeon, the greater name and prestige he can build up for himself in his community the greater his value to the industry with which he is connected and the greater his influence over the employees and their confidence in him.

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Seventh Annual Session of the American Medical Association, Detroit, June, 1916.

* This article and the one by Dr. Clark which follows are parts of a symposium on Industrial Medicine. The remaining articles by Drs. Lemon and Smith and the discussion will appear in THE JOURNAL, January 13.

THE WORK OF THE MEDICAL STAFF: PREVENTIVE SURGERY

Those engaged in emergency accident work for any industry are naturally trained, by the very nature of the work, to view every case from the economic standpoint of both the employee and employer. An accident occurs, and at once we plan the subsequent handling of the case with these four fundamental principles in mind: (1) how to prevent a recurrence of the accident, (2) how to aid recovery the quickest, (3) how to prevent permanent disability, and (4) how to avoid a fatal termination of the case.

The welfare of the patient, the protection of the other employees, and the interests of the employer all demand the careful consideration of these principles.

The evolving of the simplest and yet most adequate methods of enforcing these four principles is the foundation of preventive surgery. And just as prevention of disease will eliminate some surgery, so the prevention of accidents will eliminate vastly more, and the best surgeon of the future, whether engaged in industrial work or otherwise, will be the surgeon who is very conservative in operating, but very radical in the prevention of all causes that make surgery necessary.

The safety engineers with their safety appliances and the educational propaganda of all safety first movements have been instrumental in preventing a great many accidents, especially from machinery. But the alert emergency surgeon, by carefully analyzing the cause of every injury that comes to him for treatment, and then by cooperating with the safety engineer, making certain that that cause has been removed, becomes one of the greatest factors in all accident prevention. Very often the cause for the accident lies within the employee himself, in his physical or mental condition at the time it occurred. It is therefore the paramount duty of the surgeon to carefully analyze the condition of that employee in his search for the cause. This analysis must include a thorough physical examination and mental tests, and an examination of both the working and home conditions of that employee. This last duty can be performed by a competent trained nurse, who is the greatest adjunct to the company surgeon in all his work. The removal of the cause, whatever it may be, or wherever found, in every case of accidental injury that comes before him, is the duty of the preventive surgeon and is the most logical and most economic form of service that he can render to the employee or employer. And the time is not far distant when municipalities, the state, and the federal governments will awaken to the great waste of life and limb, the result of accidents, not only in industries, but in the homes, in the streets and in every branch of our daily walks of life. And we as surgeons will be required to do our share in analyzing every case of injury brought to the office or the hospital and report the same to the proper authorities, so that the cause for that accident can be removed, just as we are now compelled to report on contagious diseases. And we as surgeons will look backward with saddened hearts on these dark ages when our sole service to society was merely the repair of the frightful injury to the individual, or simply pronouncing him dead, without a single thought given to preventing some other unfortunate from suffering a similar accident.

The immediate care (and by immediate I mean within a very few minutes) of every one injured, no matter how slightly, is another most important duty of preventive surgery. The first aid movement, which is sweeping the country under the leadership of Dr. Joseph Bloodgood, is one of the best signs that the surgeons are alive to prevention. But every first aid man or woman must be taught that he is only for first aid, and every first aid kit must contain supplies only for first aid. There should be a bottle of tincture of iodin (5 per cent. is sufficient) and a bottle of applicators, a bunch of sterile dressings put up singly in envelopes or paper, a few large pads, sterilized, and to be used in case of hemorrhage or large wounds, bandages and a constrictor. The constrictor I advocate is a stout muslin bandage rather than a rubber tourniquet, as it is safer in the hands of a layman. You may add to this a bottle of aromatic spirits of ammonia with directions as to its use, but no other medicines are indicated. The industries must be taught that the safest and cheapest first aid for them to employ is a doctor in a company office located at the plant where he can render immediate surgical care to every one injured, and at the same time can supervise the health of the employees. In the outlying portions of a large plant or in the dangerous departments the employees may injure themselves in such a way that first aid is necessary until they can reach the doctor's office. In such departments in one industry I have placed first aid supplies orderly arranged in substantial looking boxes. But on these boxes, at the head of the directions for the use of the supplies, I have this warning:

> READ CAREFULLY!
>
> This is a FIRST AID OUTFIT ONLY. It is not to be used for subsequent dressings. The purpose of the *First Aid Man* is not to replace the *Doctor*.
>
> Send every injured employee to the Doctor's office AT ONCE NO MATTER HOW SLIGHT THE INJURY. Use these supplies for temporary dressings until the proper medical care can be obtained.

Two years ago I obtained statistics from a number of industries and accident insurance companies and found that it was the minor accidents, such as scratches, pin pricks, nail wounds, splinters and small cuts that caused the largest amount of disability, and this disability was usually due to infection. Infection in major injuries was comparatively rare. These facts are due to the difficulty of preventing these minor accidents, and because an employee as a rule does not seek medical aid for a slight scratch or cut until it becomes infected, whereas a serious injury forces him under the care of a surgeon at once To combat these minor accidents we have resorted to an educational propaganda against them, the removal of every possible cause for them, and the management insists and enforces the rule that every injured employee must report to the doctor at once no matter how slight the injury But the best preventive surgery measure thus far adopted is the immediate use of tincture of iodin on all wounds that break the skin Every department is supplied with from one to ten bottles of tincture of iodin and applicators (cotton rolled on the end of a toothpick) held in containers made as attractive as possible and placed in conspicuous places Directions on the box tells the employee to paint every pinprick, scratch, cut, puncture wound etc, with the iodin at once and then he must report to the doctor's office at once The use of the iodin alone is not sufficient Reporting to the doctor at once is not sufficient But use the iodin at once and then come to the doctor at once Reaching the doctor may take five or ten minutes, but the use of the iodin does not take over a few seconds So it is the immediate disinfection of the wound with the application of dressings very shortly afterward that gives the results

In 1909 I first introduced this use of tincture of iodin among employees and since then it has become quite universally used among many industries Several company surgeons still raise objections to its use and cannot see its superiority over other antiseptics Many employees so have the habit of using hydrogen peroxid that it is difficult to replace this usually inert liquid with the iodin The actual figures as set forth in a previous publication[1] show conclusively that the results warrant its use From 1909 to 1912 there was a reduction of 38 per cent in the number of hand infections At that time the management became more active in enforcing these rules In 1912 out of 2,693 accident cases reporting to the doctor's office, 28 6 per cent became infected In 1915 out of 5,000 accident cases reporting to the doctor's office 10 per cent became infected Most of the infections in 1915 occurred among new employees and all of them except twenty-four failed to follow the instructions concerning the use of iodin and reporting at once Not a one of the twenty-four who used iodin were infected sufficiently to require opening, neither did they lose any time from work Thus among the injured employees who use iodin at once and report to the doctor at once, less than two tenths of 1 per cent become infected

After an accident has occurred in spite of all our methods of prevention then it is the duty of the preventive surgeon to so institute the best form of active treatment at once that he will secure the quickest recovery, the least deformity, and prevent a fatal termination Temporizing methods by the surgeon are to blame too often for great losses to both the employee and employer By temporizing methods I mean trying office treatment or home treatment when the best hospital treatment should have been instituted at once, failing to watch carefully for the earliest indications of threatening complications, leaving the patient too much to the care of an assistant or an intern, and failing to take advantage of every known means of diagnosis and of every known method to attain the quickest and best results

PREVENTIVE MEDICINE

The common aim of preventive medicine and preventive surgery is so obvious, and yet it is only recently that the two have been mentioned in unison It was left to the work of a few company surgeons scattered over the country to bring out the indivisibility of the two A comprehensive plan for the supervision of the health of employees if adopted by all industries would be the greatest movement in this country for preventive medicine, and at the same time would be the greatest safety first movement that they could install Here again a temporizing plan will not yield the best results The medical staff must do its medical and sanitation work thoroughly and completely A mere inspection of employees must not replace a thorough medical examination because it takes less time and is immediately cheaper for the employer, work that should be done by the doctor must not be left to a nurse or trained lay assistant, and conditions in the employees that mean a premature retirement to the scrap-heap must not be tolerated because to correct them means an immediate loss of time Even temporizing methods, it is true, are better than the old methods, which did not consider in the least the health or life of the employees, but the company physician today must show that the benefits to the employer are in direct ratio to the thoroughness and completeness of the plan which he adopts for the supervision of the health of his employees

The thorough medical examination and reexamination of each individual is the chief aid in supervising the health of any group of people in intimate contact with each other, therefore, every employee in the active working force should be examined for the following purposes

1 To ascertain the condition of health of each employee and to give personal advice to those who need it, along the lines applicable to their cases

2 To discover diseases among the employees in the earliest stages and therefore while still curable Many diseases of which there was no knowledge are thus discovered, and the afflicted employee is advised as to methods to overcome the trouble or at least to prevent its advancement Many of these are referred to the family physician months before the patient would voluntarily seek his counsel

3 To find any one who has contracted a disease that might be communicated to a fellow employee Tuberculosis is the chief of these diseases Not only is the working force protected from contamination, but the disease is usually found in such an early stage that practically always a cure is possible

4 To discover the chronically diseased employee who is still able to work, and to recommend for him a position where he will be efficient and which will not hasten the course of his disease Thus, the man with organic heart disease would be an inefficient heavy trucker and such work would be of great danger to his life, whereas he would make a good straw-boss or light packer, positions which would enable him to control his disease

Likewise the medical examination of all applicants for work should be made, not for the purpose of choosing only the strongest, healthiest workers, as such a plan would be too great an injustice to our weaker fellow men, but for the following reasons

1 To prevent those with contagious diseases from mingling with our healthy employees

---

[1] Mock H E Treatment of Hand Infections from an Economic Viewpoint Surg, Gynec and Obst 1915 21, 481

2 To prevent those with serious diseased conditions from going to work, for their own protection

3 To choose the proper type of work for those with some chronic disease which does not totally unfit them

Next in importance to the medical examination in supervising the health of the working force is the personal contact between the doctor and each employee, which enables him to advise concerning all matters of health and means of prevention which are suggested by their individual cases Thus, they are told when a diseased condition is present and how best to overcome it and when they should consult their family physician They are warned against wrong lines of treatment and the dangers of consulting quacks and advertising doctors, and the uselessness of taking 'patent medicines " The personality of the doctor is a most important factor in this personal contact with the employees He must be a friend, a teacher, and a kindly adviser at all times in order to gain their absolute confidence

Arguments have been raised against the medical examination of employees, chiefly by leaders of labor unions They say that unscrupulous employers could adopt such a system for the elimination of all but the very healthiest, and most efficient employees, or for the elimination of undesirable employees among the union help These objections are worthy of weighty consideration, if any employer adopts this plan from such an inhuman standpoint But if hand in hand with this medical work there is constructive work on the part of the employer to better the sanitary conditions of the working place, to assist the employee to regain his health, and so to regulate his work that it will not be detrimental to him, then these arguments are at once completely nullified

We have thoroughly examined employees during the last seven years [2] During the last three years we have also examined all applicants for work [3] For the years 1914 and 1915 we examined 15,151 old employees, 27 per cent of whom were found with definite diseased conditions, while a great number of very minor defects were found but not classified None of these employees were discharged, but they were advised as to the best methods to overcome or control their diseases, many were given vacations, or free hospital or sanatorium care, others were referred to their family physicians, or when investigation proved they could not afford to pay for special care, this was rendered to them free of charge by the medical staff Whenever the work of an employee was found to be detrimental to his health he was transferred to some other position as a rule his health improved and he became a more efficient employee at once In the matter of tuberculosis among our employees we have cared for 284 patients free of charge, a majority of whom were treated at sanatoriums

During the same period of 1914 and 1915, 13,764 applicants for work were examined and 19 9 per cent had definite diseased conditions, but only 3 4 per cent of these were rejected for employment In every case a rejection was made only when the applicant had some diseased condition which made work at the plant detrimental to him, or some contagious disease which might be spread to the active working force These figures and these facts are the strongest rebuttal we can possibly give to the arguments advanced against such a humane system of preventive medicine

But when such a system becomes more universal, great hardships will fall on the 3 to 5 per cent physically unfit employees who are unable to secure employment because they cannot pass the medical examinations Because of these hardships we are brought face to face with another problem which must always go hand in hand with any system of universal supervision of the health of employees, namely, either state or federal control of such a system and either state or federal health insurance laws, insurance against nonemployment, and old-age pensions But these same laws must be so carefully worked out that they will not react as a hardship to some other branch of society, and it therefore behooves the physician to devote much time and attention to this subject

The sanitation work, the ventilation, the study of temperature and of humidity, the disinfection of departments in which contagious cases have developed the disinfection of toilets and of cuspidors, and all matters dealing with the sanitary conditions of the working place make up a large portion of the work which must come under the direction of the specialist in industrial medicine and surgery

Likewise, the personal hygiene of each employee, his exercise and recreation, his housing conditions and the home environments, his personal habits and even his family history are matters which must be included in the scope of this work

The industrial visiting nurse, who also must have a vision and a social sense, is responsible for the investigation of many of these latter problems, and no plan of medical supervision of employees can be complete without her assistance Also the industrial dentist is coming more and more into this work as an aid in upbuilding the health efficiency of the employees A human laboratory for work and research in practically every branch of medical science is found in this field of industrial medicine and surgery And the company surgeon who takes advantage of it is destined not only to become a skilled, conscientious physician and surgeon, a sociologist, and an economist, but the influence of his work extends from the shop walls to the entire community

---

Parinaud's Conjunctivitis—Surg G L Collins, U S P H S, in *Public Health Reports,* Dec 15 1916 says the health officer should keep in mind Parinaud s conjunctivitis in his search for trachoma Although he may regard granulations of adenoid tissue in the tarsal conjunctivae and retrotarsal folds as almost pathognomonic of trachoma, several other conditions, as Parinaud's conjunctivitis, may closely simulate trachoma Collins reports a case in a vigorous young woman, a gymnastic teacher, in whom the conjunctiva of each lid was greatly congested and at the nasal side of the upper lid were many granulations, and also in the upper retrotarsal fold, where they were crowded close together The granulations had a peculiar, yellowish semitranslucent appearance, and examination with a loupe showed minute white areas on the surface, with considerable mucoid secretion, but no pus A few granulations could also be noted on the epicanthal fold, and a minute subconjunctival hemorrhage on the bulbar conjunctiva The condition was unilateral and there was an enlarged and tender preauricular lymph gland The other eye was normal There were slight constitutional disturbances The symptoms were characteristic of Parinaud's conjunctivitis, and subsided in two or three weeks under simple treatment *The source of the infection could not be determined*

MEDICAL SUPERVISION OF FACTORY EMPLOYEES

RESULT OF FIVE YEARS' EXPERIENCE[*]

W IRVING CLARK, Jr, MD
WORCESTER, MASS

The basis of this paper is work done in the Department of Health and Sanitation at the Norton Company and Norton Grinding Company, Worcester, Mass , from May, 1911, to May, 1916

The medical department in a factory has five functions, as follows

1 To make physical examinations of all prospective employees, and reexamine all defective employees
2 To treat accidents immediately after they occur—and subsequent treatments
3 Examining and advising cases of sickness
4 The control of sanitation throughout the works
5 Health publicity

I will take up these functions in order, and discuss each one briefly, giving our results

PHYSICAL EXAMINATIONS

The best time to make a physical examination is before the employee is hired This immediately eliminates any man who is totally unfit for the work to which he is assigned, and prevents contagious diseases becoming established in the shop Rejections should, however, be made only when they are absolutely necessary, as many men are perfectly capable of doing work in certain departments though unfitted for work elsewhere A physical examination should be made not only on a prospective employee but also on each employee who is transferred from one department to another for reasons just mentioned Periodic examinations, about once in six months, should be made on all men having defects of a nature which is serious enough to require inspection

Completeness of Examination—We believe that examinations cannot be made too complete When the department started, there were certain examinations which we did not consider necessary, such as examinations of the feet, and blood pressure We have since, however, changed our minds as a result of experience We now believe that the applicant should be completely stripped at some point during the examination and that as thorough examination should be made as in a general hospital on the admission of any medical case We consider blood pressure a distinct advantage as an indication of possible trouble in the kidneys This is especially valuable as a time saving device, being much quicker, and simpler than making a urinalysis of all cases Our rule is to do blood pressure on every man over 20, to do urinalysis on every person under 40 who has a systolic pressure of 150 or over, or a diastolic of 100 or over all men of over 40 years have a urinalysis regardless of their blood pressure

REJECTIONS[1]

We arbitrarily reject

1 All applicants over 45 years of age
2 All men having only one eye This because the work about grinding wheels is particularly hazardous to the eyes, even when goggles are worn
3 All men having vision reduced to ½ in both eyes
4 All cases of contagious disease, including, of course, tuberculosis
5 All cases having more than a second degree hernia (using the classification of the Conference Board of Physicians in Industrial Practice)
6 All cases of heart disease with disturbed compensation,
7 All cases of varicose ulcer
8 All cases of fourth and fifth degree flatfoot where the arches apparently give trouble
9 Marked hypertension

We have worked out this list of rejections by rule of thumb Each cause of rejection has been gone over most carefully and has been decided on only as a result of actual experience

Since Nov 1, 1915, we have made 100 rejections During the same period of time we have examined 2,618 applicants The causes of rejections are given in Table 1

TABLE 1—CAUSES FOR REJECTIONS

Causes	Number
Age (over 45 years)	20
Eye defects	35
Heart defects	2
Lung defects	4
Hernias	32
Venereal diseases	2
Nephritis and hypertension	3
General (numerous defects)	2
Total	100

There has been some question as to the selection of 45 years as a rejecting age Analyzing the physical examinations of the men rejected on account of age we find the gross defects given in Table 2 All of these defects are enough to disbar a man even though his age came under our limit

TABLE 2—DEFECTS IN APPLICANTS OVER 45

Defects	Number
Defects of eyes	9
Defects of ears	6
Defects of hearts	6
Hernias	5
Nephritis and hypertension	9
Pronounced flatfoot	2
Varicosities	1
Defects of lungs	1
Total number of defects	39

In other words, in twenty men over 45 years of age we found thirty-nine defects sufficient to disbar the applicant even if his age were under 45

DEFECTS FOUND IN EMPLOYEES THAT DO NOT BAR THEM FROM EMPLOYMENT

There are very few men who apply to the Norton Company for work who have no defects The average workman, though having numerous slight defects, is perfectly capable of doing almost any work in the factory There are, of course, some departments in which restrictions are higher than others — departments where there is considerable heat, heavy lifting, and more than the average amount of dust In these departments we try to get the most absolutely fit men that we can procure, provided they have the mental capacity for doing their work Examining the mental capacity of the prospective employee is a function of the employment department and does not come under our jurisdiction During the first three months of 1916 we examined 1,379 prospective employees Forty-three of these were rejected for reasons just given The last thousand consecutive cases showed the minor defects indicated in Table 3

The cases of tuberculosis existed among those who were rejected, and many of the persons with hernia were also rejected Each one of these prospective employees was told of his defects, and wherever possible instructions were given to show him as to how this defect might be remedied or be kept from troubling him It may be interesting to note that several patients with hernia have since our notification gone to the Worcester City Hospital, had curative operations and later become employees of the Norton Company Several other employees having marked defects of both eyes have procured glasses remedying these defects, and have been placed in departments where there is no danger of foreign bodies getting in the eyes

---

[*] Read before the Section on Preventive Medicine and Public Health at the Sixty-Seventh Annual Session of the American Medical Association, Detroit, June 1916

[1] Rejections are made by employment department The term "rejections" here refers to medical risk as reported to employment department

TABLE 3—MINOR DEFECTS

Defects	Number
Defects of the eyes	100
Defects of the ears	23
Defects of the nose	148
Defects of the throat	35
Defects of the teeth	569
Defects of the neck	16
Defects of the heart	62
Defects of the lungs	17
Defects of the extremities	339
Defects of the inguinal region	106
Genito urinary defects	53
Defects of the spine	3
Defects of the skin	24
The more serious defects consisted of	
Defective vision in both eyes	56
Endocarditis, mitral insufficiency	41
Pulmonary tuberculosis, active	3
Flatfoot	311
Hernia (second degree or more)	50

Blood Pressure — Our experience with blood pressure has tended to confirm the general experience where large numbers of blood pressures were taken In the last thousand cases, dividing the men by decades we found the average as given in Table 4

TABLE 4—BLOOD PRESSURE

Age Years	Systolic	Diastolic	Pressure Pulse
From 20 to 30	129 5	88 5	50 3
From 30 to 40	135 1	89	47 2
From 40 to 45	140	91 6	48 2
From 45 to 50	158 8	92 8	66
From 50 to 60	167	100 8	72 5
From 60 to 65	178	100	77 5

I believe that the average systolic pressure is a trifle higher than normal on account of the excitement of the examination This fact has been brought out by Dr Roger I Lee, who came to this conclusion after examining the Harvard medical students The averages, however, are pretty much within normal limits It is rather interesting to note the increasing pressure pulse as age increases, remaining about the same for the first three decades and then rapidly climbing

To sum up the result of five years' experience with physical examination of employees in a factory of about 2,800

1 The average workman does not object to physical examination, and the majority of them are pleased to have such an examination made

(*a*) On account of the *information it gives them*

(*b*) Because it throws them in intimate contact with the doctor to whom they are going to apply afterward in case of sickness or accident

2 A physical examination cannot be too complete The most complete form of examination the average man requires takes ten minutes, provided a urinalysis is not done

3 Periodic examinations of markedly defective men tend to keep such employees in good condition and prevent an increase in their defects

4 As it is impossible to employ men who have no physical defects, a physical examination enables us to place men in departments where they will suffer the least risk and maintain the highest degree of physical efficiency

5 A fresh examination each time a man is transferred from one department to another prevents the possibility of a man being assigned to work for which he is not physically adapted

6 A periodic examination of the entire force once a year is not necessary because

(*a*) The examination is made each time a man is sent from one department to another

(*b*) All men having any sickness or accident apply to the hospital and are there examined if there is anything indicating the necessity for such an examination

7 The number of rejections, even with a rather highly restricted list of defects, is *very small, and is* no argument against but rather an argument for the advisability of physical examinations

HANDLING OF ACCIDENTS

All accidents *occurring* at the Norton Company and the Norton Grinding Company receive treatment in the department of health and sanitation This has been so thoroughly drilled into the foremen that we invariably see accidents within fifteen minutes of the time that they occur, except in cases of foreign bodies in the eye In these cases men sometimes do not realize that they have received a small foreign body in the eye and do not report to the hospital until the next day, when reaction is beginning The result of this prompt attention to all injuries has reduced our loss of time from accidents to the minimum during the five years the department has been in operation We have never had a case of sepsis I do not feel that I can make the statement that we have never had a case of infection, for in several cases there has been a single drop of pus, or a moderate exudation from a wound By sepsis I *mean pain, heat and redness accompanied by swelling* As we have been treating on an average of 241 accidents a month, it will be seen that the methods we use must be efficient Although these are undoubtedly those used by the majority of shop hospitals, I will give our routine

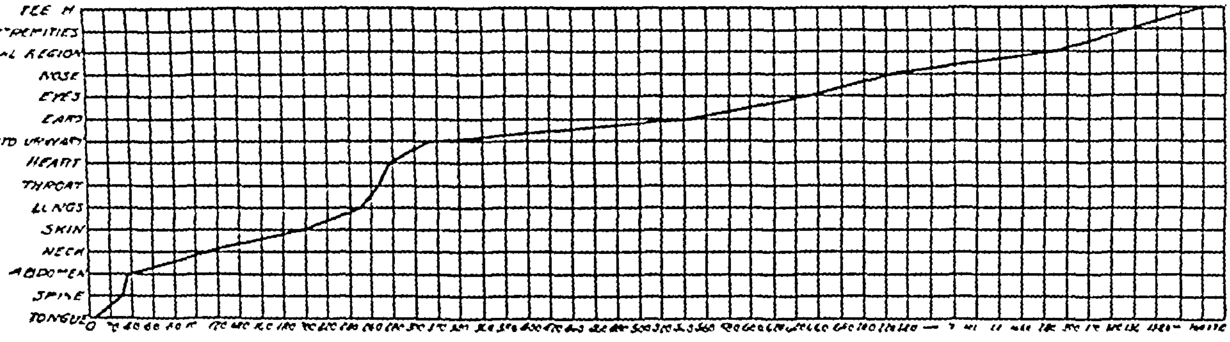
The wound is first thoroughly washed with commercial gasoline The gasoline is slushed on and used like water, being poured not only over the wound but into the wound itself, and a rather vigorous scrubbing is given the surrounding skin with sterile gauze Immediately after this, tincture of iodin, U S P, is poured into the wound and over the skin This is allowed to dry and a sterile gauze dressing is applied If for any reason we suspect the wound of being pretty dirty, a *second dose of iodin is poured on after the first is* applied My experience with this method of cleaning is not confined to the Norton Company, as I have used it in my private practice and active service in two large *hospitals As there has been some discussion as to* the efficiency of iodin, my own experience may be summed up as follows

Iodin to be 100 per cent efficient as an antiseptic must be used within thirty minutes of the receipt of a wound The efficiency decreases 25 per cent every fifteen minutes beyond this time After two hours it is almost useless

The immediate treatment of accidents undoubtedly reduces the time of disability If sepsis is eliminated, fractures promptly set, and backs strapped immediately *after strains, many patients are able to return* to work within a very short space of time in spite of apparently severe injuries

During the month of April at the Norton Company we treated 474 accidents, but one of which was severe enough to draw compensation That is, there was only one man injured severely enough to keep him out of work over fourteen days During the year from May 1 1915, to May 1, 1916, we treated 2,895

The facilities of the shop hospital for the after treatment of accidents has never been thoroughly brought out The peculiar situation of the shop hospital enables it to get a rapidity of cure in both accidents and sickness which cannot be reached by any other method There is no other method of treating ambulatory patients by which the patient can be brought to the doctor at a moment's notice and by which as many treatments as are required can be made during the day The two weaknesses of the general hospital outpatient department are first, that the patients frequently do not follow advice or fail to report and second that in cases requiring redressings these must be done by the patient at home The shop dispensary, however provides a place where the men may have dressings done in the shortest possible time by the most competent dressers, and by a follow-up system it can be definitely arranged that a patient will report at regular intervals through the day for such dressings



Number of defects and regions affected found by examination of 6 000 employees

I have been surprised at the speed with which infections clear up when treated in this way As I mentioned in my previous section, we have had no sepsis from any accident, but in many cases we have had men apply to the shop hospital with infections which they have incurred from neglected wounds occurring outside the works when home treatment has been used Furunculosis is very common, and we have, I regret to say, a number of cases of foreign body in the eye in which the patient has not realized that the foreign body was present until twenty-fours or more have elapsed Four-hour dressings of infections will, I believe, curtail the time of disability almost 50 per cent, and, moreover, the employee will keep on working because he knows he will get attention with little loss of time In foreign bodies of the eye, after the foreign body has been removed, we have the patient report every three hours to receive hot compresses and instillations of argyrol We seldom have an eye which is not cured completely in forty-eight hours, and in the majority of cases men lose no time while the treatment is being carried on The same applies to some medical conditions, particularly tonsillitis and other forms of sore throat In these cases we paint the throat two or three times a day with iodin and glycerin, providing a hot gargle for the patient every three hours

To sum up, our experience with accidents in the last five years has convinced us that 1 A very little inducement will bring every accident, no matter how slight, to the shop hospital for treatment 2 The shop hospital is the place to treat accidents of all kinds, and first aid should not be done in the shop unless it is absolutely necessary to save life 3 Gasoline followed by tincture of iodin is the best antiseptic, and if used within fifteen minutes is practically sure of producing a clean wound 4 Safety engineering has reduced the number of serious accidents to the absolute minimum, but is unable to reduce the very slight minor cuts and smaller injuries, the latter depending on the personal element of the employee

TREATMENT OF SICKNESS

Our treatment of sickness is prophylactic, not curative When a man is sick enough to need a doctor we send him to his family physician or to the hospital If he has no family physician we give him a list of doctors from which to choose Our idea of handling sickness is to make a correct diagnosis and to treat the minor ailments which if not attended to promptly may lead to more serious conditions Such cases are sore throat, coryza, beginning bronchitis, constipation, diarrhea muscular pains and similar slight ailments For such treatment we have a small supply of simple drugs which in the majority of cases is efficient If we have to treat a man more than twice for a condition requiring medication, we immediately advise him to go to an outside doctor Any man who is really sick we endeavor to diagnose, but do not attempt to treat him ourselves When a man has a temperature of 100 4 he is sent home and not allowed to return to work until he has presented himself to the hospital in perfect condition I wish it to be distinctly understood that I do not believe the function of treating sickness belongs to the average shop hospital, but I do believe that many diseases may be prevented by immediate simple treatment, by observation and advice As I have before said, I like to consider the medical function of the shop hospital as a diagnostic clearing house

During the past year we have treated 3,474 cases and have, I believe, materially reduced the disability from sickness, by simple preventive measures

To sum up

1 Our treatment of sickness is preventive, not curative

2 Our effort in serious sickness is to diagnose and see that the man gets immediate attention from his family physician or from a specialist where one is indicated

3. We believe that a man with a temperature of 100.4 should not be allowed to work and should not be allowed to return to work until his temperature has reached normal and all signs of the disease have disappeared.

4. By arranging that all men feeling sick must come to the shop hospital, we have prevented a large amount of sickness and have isolated a number of contagious diseases in the last five years, besides in many cases saving life through early diagnosis in such cases as acute appendicitis.

6. Such treatment will materially reduce the time lost by employees throughout the shop.

We believe the follow-up system by which the absent employee is visited by a member of the employment department when reported from work is of the greatest value to the medical department. In this way we can be sure that (*a*) no man has received an accident and failed to have it cared for at the medical department; (*b*) an employee has not a contagious disease which is unknown to the medical department; (*c*) an employee is sick and has not received adequate medical care on account of his financial condition; (*d*) a patient who has been coming regularly to the hospital is not absent from work because of some trouble arising from the injury.

The follow-up system, therefore, has a double function. First, to hunt down the men who are absent with the idea of getting them to return to work as soon as possible, and second, to investigate any patients absent on account of sickness or accident, and to report the same in detail to the medical department, so that the medical department may take further action.

The control of sanitation should rest entirely with the medical department.

At the Norton Company the entire cleaning of toilets, wash-rooms, as well as the removal of rubbish, garbage and paper is in the hands of the department of health and sanitation. In this way the work is centralized and can be systematically arranged so that each man of the force has a definite round of work to perform. Although the company has been expanding greatly in the last two years, and as a result the toilets and wash-rooms have been badly crowded, thanks to careful, systematic work there has been no complaint whatever. One of the things with which we have had most difficulty is to find a good type of cuspidor. The one which we now use is made of stone, is almost unbreakable, and cannot be upset. It is filled with sand and chlorinated lime, and has proved absolutely satisfactory.

HEALTH PUBLICITY

Much educational work can be done throughout the shop by means of leaflets written in simple, clear language on the subject of hygiene and general medicine. We have been publishing such leaflets monthly, enclosing them in pay envelopes, and their reception has been most gratifying. The best bulletins of this type are probably those recently approved by the Conference Board of Physicians in Industrial Practice.

37 Pearl Street.

Feeblemindedness.—The term feebleminded is used generically to include all degrees of mental defect due to arrested or imperfect mental development, as a result of which the person so afflicted is incapable of competing on equal terms with his normal fellows or managing himself or his affairs with ordinary prudence.—American Association for Study of the Feebleminded.

THE PREVENTION OF CHRONIC MIDDLE EAR SUPPURATION*

GEORGE W. MACKENZIE, M.D.

PHILADELPHIA

When we consider the frequency with which it occurs, the resistance it offers to treatment, the damage it does to hearing, and the risk it incurs to the life of the individual, the subject of chronic middle ear suppuration becomes one of importance, and the question of how best to prevent it deserves the time and attention of the section that the chairman has seen fit to assign to it.

The prevention of disease is the highest aim of the medical profession. To accomplish successfully this aim we must possess first a knowledge of the disease that we hope to prevent. A comprehensive knowledge of any disease implies a knowledge of the pathology and diagnosis. This applies especially to the subject of chronic middle ear suppuration, for the reason that it is a disease capable of manifesting itself in a variety of ways and liable to many complications. It is not only necessary to recognize the disease when present, but we must actually anticipate it when certain factors are favorable to the development of the disease. Thus we see that a knowledge of the etiology is even more important than a knowledge of the pathology and diagnosis, in that it goes a step farther.

These requirements, a knowledge of the etiology, pathology, and diagnosis, are necessary if we hope to prevent chronic middle ear suppuration.

A knowledge of the diagnosis is essential, for without it we can know nothing about the condition which we are attempting to prevent, nor are we able to say that a particular case is chronic or acute. For instance, when a patient presents himself for treatment with the history of a running ear lasting over a prolonged period, the diagnosis of chronic middle ear suppuration may be inferred, but should not be concluded, for the evidence is insufficient. The diagnosis must include a knowledge of every feature of the case ascertainable from all available sources of information, including the history, the functional hearing and static tests, the otoscopic examination, the rhinoscopic examination, the skiagraphic examination, the examination of the secretions from the middle ear for consistency, color, odor, etc., the microscopic examination of the washings from the ear for cholesterin or other crystals, for micro-organisms, including the smear and cultural methods of examination in order to ascertain the nature of the infecting organisms, blood and urinary examinations, in many cases a neurologic examination, and indeed occasionally a general physical examination of the entire body. There is no disease that requires a more exhaustive examination. By such complete methods only are we able to determine, with some degree of certainty, the pathologic conditions that exist in the middle ear, eustachian tube, attic antrum region and mastoid cells, whether the suppuration is an acute or chronic process, whether it is tending toward spontaneous recovery or extension, whether the extension is toward the inner ear or intracranial structures, whether cholesteatoma is present or not, whether the suppuration in the middle ear is producing a detrimental effect on the patient's general condition of health or vice versa. Besides, from the knowledge obtained by a thorough examination combined with experience gained in similar cases, some idea may be formed as to the prognosis with and without treatment and the probable effects of selected treatment. I use the words "selected treatment" advisedly, for the reason that treatment cannot be routine in a disease in which the conditions are so variable as they are in chronic middle ear suppuration.

---

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty-Seventh Annual Session of the American Medical Association, Detroit, June, 1916.

We have referred to the importance of a comprehensive diagnosis and how the diagnosis depends in a large measure on our knowledge of the pathology, but only in a direct, physical-mathematical sort of way, as determined by laboratory methods. On the other hand, the indirect (predisposing) symptomatic, and, we might add the physiologic factors as determined by clinical methods, are not included in the study of pathology. It is these latter features that play an important role in the individual susceptibility and variability in the manifestations and course of the disease so that it would hardly be fair to dismiss the subject of etiology with a mere reference to the pathology.

Since chronic middle ear suppuration is the sequela of acute middle ear suppuration, the prevention of the chronic form is possible only when we are able to arrest the suppurative process while it is still in the acute form. Just how long an ear may discharge before we may class the condition as a chronic middle ear suppuration is a question difficult to answer. Probably no two authorities would agree. It was taught in the Politzer clinic that an ear that discharged for more than two years might be classed as a chronic condition and should be operated on radically, while a discharge lasting for a shorter time was classed as acute and should be operated on after the simple method. Politzer then cited a limited number of exceptions to this rule.

The question of duration is a relatively important one when considered along with other factors, more especially the influence of treatment. For instance, if an ear continues to discharge for more than six months in spite of carefully conducted conservative treatment covering a period of two months or more the writer would be inclined to consider the case chronic, but not necessarily one requiring radical operation.

The treatment of acute middle ear suppuration depends on many factors, local or distant, recent or remote, the presence or absence of complications, the susceptibility of the patient to a particular infection, and the vitality of the patient, measured by his general resistance to all diseases and his power of recuperation.

Local factors that tend to prolong a case of acute middle ear suppuration may exist in the form of adhesive bands in the middle ear spaces, left there by one or more previous attacks of acute secretory catarrh, narrowing of the eustachian tube anywhere along its course, the result of organized exudate following acute secretory catarrh. Anything which tends to obstruct the free drainage of pus from the middle ear spaces becomes a factor of importance in prolonging an acute middle ear suppuration. The normal route for the escape of middle ear discharge is down the eustachian tube, which is at the same time the most favorable. The reason why discharge finds its way out through a perforation in the drum membrane in the case of acute suppuration of the middle ear is because the normal route down the tube is temporarily closed. It follows, therefore, that when the normal route continues closed beyond a certain period, the suppuration tends to last proportionately long. Drainage down the eustachian tube may be obstructed by inflammatory edema of the mucous membrane, but this is usually transient. The more important obstructions are the organic, and the most frequent of these is to be found in the narrowing that follows the organization of exudate from acute tubal catarrh. The loss of the cilia with metaplasia of the epithelium, in spite of patulousness of the tube, may act as a relative obstruction in that drainage is not favored, as is the case when the epithelium is in normal condition. Very large adenoids may obstruct the orifice of the tube and interfere with normal drainage. A frequent location for obstruction is to be found at the upper end of the tube, or, more properly speaking, in the pretympanum. In this location membranous diaphragms are sometimes formed. The opening in this diaphragm may vary in size at different times in the same individual.

Obstruction in the middle ear cavity may be found in the form of so-called adhesive bands, which tend by their presence to close off partially dead spaces. In one case it may be the attic region, in another the antrum region, and less frequently the hypotympanum. These bands may exist from birth, due to incomplete absorption of the connective tissue that existed there in the embryonal state. More often it is due to the deposition and subsequent organization of exudate following a catarrhal condition. It is this same process that leads eventually to the so-called chronic adhesive process of the middle ear. When the adhesive bands tend to close off the antrum the possibility of complicating mastoiditis is increased. The way to the antrum, instead of being closed off by material bands, may be concentrically narrowed by the organization of exudate from similar causes. Temporary closure, partial or complete, of this region may result from inflammatory swelling of the mucous membrane. The perforation in the tympanic membrane may be too small or unfavorably located to permit of proper drainage, in which case it would be well to enlarge it. My impression is that far more attention is paid to the size of the perforation in the membrane than to the condition of the tube, when in fact obstruction in the tube is by far the more important factor of the two when both conditions are present. The first place to look for imperfect drainage is in the tube, correct it and the size of the perforation often becomes a factor of secondary importance. On the other hand, I do not wish to criticize any one for giving attention to the size of the perforation, but rather for neglect of the tube. Anything that obstructs the free flow of pus from any part of a suppurating middle ear tends to prevent spontaneous recovery and therefore to chronicity. The exact nature of the obstruction should be sought and corrected by the simplest known method. If the obstruction is due to necrotic areas in the bone, with granulations, or to cholesteatoma, or to large polyps, the condition is already chronic, and a discussion of them would be foreign to our present subject.

When the obstruction can be located and its nature determined, the logical thing to do is to remove it, if possible, by the simplest means at our disposal. When these fail, as they do at times, more radical methods must be adopted, for neglect of drainage will surely result in chronicity if not complications. The question of correcting an obstruction narrows itself down to the diagnostic judgment of the otologist in locating it and his manipulative skill in handling it when it is located One thing that I have observed and wish to emphasize is the frequency with which local inflammatory swellings acting as obstructions clear up promptly after a simple mastoid operation In other words, a simple mastoid operation will side-step an otherwise irremovable barrier to drainage Nor is this to be wondered at when we consider that an organic obstruction located between the middle ear cavity and the antrum will drain the posterior spaces better by a posterior opening, while the anterior spaces will drain better anteriorly

A mastoid operation is not to be urged except when other more simple methods have been tried and have failed On the other hand, the operation should not be postponed in the presence of the indications for operation By temporizing we may fail to clear up the case by the simple operation and thus necessitate a more radical operation later

Among the neighboring and more distant conditions that may tend toward prolonging an acute middle ear suppuration may be mentioned adenoids, when extremely large, by blocking the pharyngeal end of the eustachian tube This has been referred to previously when discussing the question of drainage Aside from the fact that enlarged adenoids may act mechanically to obstruct drainage, they may menace the health of the ear in other ways For instance, the presence of adenoids increases the susceptibility of the patient to infections, and these again tend to increase the size, for the time being, of the already enlarged adenoids By this means it not infrequently happens that the patient with an acute middle ear suppuration experiences aggravations and added infections from repeated colds, furthermore, the original infection in the nose and throat is prolonged because of their presence When such conditions prevail it is important to remove the adenoids at a time best suited to the circumstances

Enlarged and chronically diseased tonsils act in a similar manner, but less directly than do enlarged adenoids Chronically enlarged tonsils are more susceptible to acute infection than normal tonsils and there is no telling just when a flare-up is going to occur, so that in a case of acute middle ear suppuration that does not tend toward recovery within a reasonable time it is a safe plan to remove the enlarged tonsils along with the adenoids Success does not always crown our efforts for the reason that there may be other factors tending to make the case chronic

Nasal obstruction may seem to some a far-fetched cause of chronicity in middle ear suppuration Nevertheless, experience teaches us that the correction of nasal obstructions act beneficially in all pathologic conditions of the middle ear Different theories have been advanced to account for it, which I will not take your time to discuss at present The importance of nasal obstruction in its bearing on suppurative middle ear conditions, although previously recognized by the writer, was further emphasized about a year ago, when, after failing to clear up a case of subacute middle ear suppuration within a reasonable time by the usual conservative methods, the condition promptly cleared up after a submucous resection of the septum performed by another physician to whom the patient had gone Embarrassing as it is to confess it, the case is cited because of the lesson it teaches

A common cause for delayed recovery in acute middle ear suppuration is to be found in the so-called chronic infections, tuberculosis and syphilis, especially the former A large percentage of the persistent cases of acute suppuration in infancy are tuberculous, when we frequently find the ear conditions associated with enlarged cervical lymphatics In some of these cases the ear condition had its origin in a tuberculous infection in the middle ear, perhaps masked by the mixed infection that usually follows the breaking down of tubercles In other cases the primary condition in the ear was due to some other infection, the process never becoming tuberculous, however, the tuberculosis elsewhere in the body acts detrimentally to the health in general and prevents prompt healing of the suppuration in the ear Early evidence of caries suggests a tuberculous process in the middle ear

In either event, care of the ear alone will generally fail to bring about a cure The case should be treated as one of tuberculosis, along general lines, as in the case of tuberculosis in other parts As is well known, the operative treatment of tuberculous ear conditions is prone to be followed by tuberculous meningitis, especially where the patient's general health is ignored

Concerning syphilis of the middle ear much less is known and fortunately the condition is rare, but the same remarks apply in a general way to this process as to tuberculosis Diabetes is prone to delay healing in acute middle ear suppuration if it does not actually contribute largely to its etiology It should be suspected in all patients over 40 years of age when there is delayed recovery of suppurative processes generally, including those in the ear Sequestration of the labyrinth as a whole or in part calls for a careful urinary examination for sugar and acetone To treat successfully the ear condition attention must be given primarily to the diabetes

It is needless to cite all the conditions that may contribute to chronicity in acute middle ear suppuration, suffice it to say that any disease of the kidneys, heart, lungs, gastro-intestinal tract or elsewhere which tends to depreciate the patient's health and vitality tends also to prolong acute middle ear suppuration and make it chronic, while any form of treatment directed toward the correction of these organic conditions contributes to the healing of the middle ear suppuration Lack of vitality may exist from known causes, including some of those already mentioned, besides lack of proper hygiene, improper clothing, insufficient nourishment, etc , furthermore, lack of vitality may result from unknown causes often inherited, general weakness due to lack of care of the mother, alcoholism in the parents, etc The child need not be puny as an evidence of lack of vitality, for on the contrary it is sometimes fat, however, a flabby fat Lack of vitality is also found in the feebly old

Lack of vitality manifests itself in two ways First, by the lack of reaction to disease, the case showing asthenic from the start There is but slight general reaction, shown by the relative lack of fever and scarcity of symptoms There is but slight local reaction, the swelling of the parts is but moderate and the pain insignificant, while the patient's wants are few Nevertheless he looks sick and is sick The tendency is for the infection to spread rapidly, it does not become circumscribed by the normal process of lymphocytosis

Another manifestation of lack of vitality is evidenced by the manner, or rather lack of manner, in which the patient responds to treatment Remedies aimed at stimulating the patient generally or the parts locally fail to do so, but more often have the opposite effect, when the prognosis becomes bad indeed

Complications by way of extension of the suppurative process to neighboring parts may be a cause for delayed recovery in acute middle ear suppuration The most frequent extension is to the mastoid cells, with resulting mastoid abscess, less frequently to the internal ear, the lateral sinus, the dura and other membranes of the brain and the brain itself It would take entirely too much time to discuss these various conditions in a limited paper Nevertheless, they are important factors that deserve careful consideration and study, and should be borne in mind, if not anticipated, in all cases of delayed recovery This calls for a searching examination, suggested in the earlier part of the paper, for by it alone are we enabled to approximate an exact diagnosis in the full sense of the term

It may be well to mention the fact that none of the complications arise suddenly, even in those cases in which they appear to, for on the contrary we generally find prodromal symptoms of longer or shorter duration These prodromal symptoms are generally due to a serous form of inflammation due to the action of bacterial toxins that filter through the bony partition that separates the infected area from that which is threatened For the alert diagnostician, therefore, sufficient time is generally allowed to intercept the more dangerous suppurative form of inflammation

Susceptibility to a particular organism, lack of immunity or failure to generate proper immune bodies in sufficient quantities may be a cause of chronic middle ear suppuration Theoretically the vaccine treatment should be ideal for this condition In behalf of this treatment a great deal was promised a few years ago I almost hesitate to confess what little service the treatment has been to me I tried it early and carefully and over a long period, and was encouraged at first, thinking I had at last found a panacea, but later disappointment came and the disappointments were repeated Autogenous vaccines were used when the time and circumstances permitted, when they were not used the stock preparations were When the results were apparently most brilliant with the vaccines the conditions were favorable and the same results were duplicated in other cases in which vaccines had not been used In the most trying cases the vaccines failed me as did other methods There is a field for vaccines, but it is a limited one I have not given up their use, in spite of my many failures to obtain results with them If the preparation of the vaccines is all right, failure to obtain results would seem to show that we are not on the right track, and the cause of the chronicity must be sought in some other factors previously referred to

My effort has been merely to outline some of the causes of delayed recovery in acute middle ear suppuration, the prompt cure of which would mean the prevention of chronic middle ear suppuration

---

The Heritage of the Profession —We are a curious mixture of heredity and environment—a curious blend of optimism and pessimism Our heritage is a glorious one for we present an unbroken line of professional workers with one ideal which was old before the Christian era From the time Hippocrates taught his disciples at Cos to the present, the one great idea the one great controlling thought, has been to find the truth and having found it, to use it for the benefit of mankind The truth sought for has never been sought that it may be put to the base use of man s destruction —J M Putnam, Address before Buffalo Academy of Medicine

NONOPERATIVE TREATMENT OF OTITIS MEDIA *

NORVAL H PIERCE, M D

CHICAGO

Chronic suppurative otitis media is rather easily cured in a large number of cases if proper methods are adopted, but it is exceedingly difficult to obtain men with sufficient self-abnegation, one might say, to carry them out I refer here especially to our public clinics, in which we find that assistants do not give the attention to nonoperative treatment of chronic suppurative otitis media that they should Such work is regarded as an uninteresting grind, hence the tendency is all toward hastening these patients to the operating table

The proper treatment depends on the location of the area of the middle ear involved, that is, whether the disease is more or less located in the tube, the cavum or the mastoid portion of the middle ear, on the stratum that is involved, that is, whether it is relatively superficial, the epithelial structures being most affected, or the tissue under the epithelium, or whether it is the periosteal layer and bone You know the mucoperiosteum, as its name would indicate, serves two purposes, as a mucous membrane and as a periosteum, the bone beneath deriving its nutrition immediately from the mucoperiosteum The treatment also depends on the character of the *pathologic process*, that is, whether it is merely a pus-producing microorganism, being a streptococcus, staphylococcus, or one of the various forms of diplococci, whether it occurs as the result of diphtheria or scarlet fever, or of tuberculosis or syphilis

Tubal disease is very rarely purulent Large quantities are blown out with the catheter Purulency in a discharge from the ear means, as a rule, disease of the bone When the discharge *from the tube* is purulent, it indicates involvement of the tubal cells, a series quite separate from the mastoid system, and calls for operative intervention, *obviously, not* the so-called radical operation, but one *outside the scope* of this paper to describe The *mucus or purulent* mucus comes invariably from the tissues above the periosteal layer of the mucoperiosteum The mucus from the *cavum is exceedingly* scant, the moisture here being secreted by *the surface* epithelium, there is little or no glandular tissue *in* the cavum In the tube these structures are quite evident, being more abundant at the pharyngeal opening and decreasing as the isthmus is approached, where it is absent, and again gradually increasing toward the caval opening The perforations in the tympanic membrane from tubal disease are situated in the anterior portion of the pars tensa practically always They are usually large in chronic cases, but may be small They are central and never *marginal* in uncomplicated tubal disease, that is, an area of tympanic membrane intervenes between the perforation and the annulus In centrifuging this discharge we find no evidence of bone cells or bone chips This discharge may be quite abundant, may be quite fluid, is usually stringy and tenacious, but not purulent This discharge may continue a long time, for years, more or less, with exacerbations occasionally, diminishing to a point at which the patient scarcely notices the discharge, or completely ceasing for a time But it is chronic and continuous in many cases *The treat-*

ment should be directed to the tube These are the cases that depend for their continuance on pathologic conditions outside of the aural structures per se This has been sufficiently brought out in preceding papers Besides removing the associated pathologic conditions in the nose and postnasal space, we should get rid of the hyperplastic tissue in the tube itself This may be done by application to the tube by means of the eustachian catheter, applicator, Weber-Liel catheter or syringe Schwartze long ago recommended that in such cases the tube be syringed out This can be done through a catheter, the irrigating fluid coming through the perforations of the tympanic membrane We should, therefore, be careful in these cases to have a large perforation, a perforation of proper size made by the condition or artificially by surgical enlargement The irrigating fluid we use for this purpose should be nonirritating A normal salt solution is ideal Nitrate of silver may be applied in these cases A small wire, preferably not silver wire, one strand being wound about another, makes a very cheap and efficacious applicator for this purpose A small piece of cotton is wound on the end and this is immersed in the nitrate of silver solution, and carried to the cavum In such operations the hard rubber catheter should be employed One should begin with a low percentage, 2 5, and increase, according to the resistance of the patient, to 10 per cent This should be carried through the isthmus to the caval opening of the tube We may apply the medicament to the tube with a syringe fitted into the catheter, but this method is less effective

In a majority of cases, when uncomplicated by diabetes, syphilis, etc, or when the tubal cells are not involved, this will bring such a discharge to a close In case, however, these patients do not recover, then the question comes up whether ossiculectomy is permissible, or whether we should take away a large portion of the tympanic membrane, establish a permanent opening by way of the external auditory canal, and by some method endeavor to seal up the eustachian tube and destroy the tubal cells

Now we come to inflammations of the cavum For descriptive purposes anatomists have divided the middle ear into the tube, the cavum and the mastoid cells As regards the pathology, these divisions do not hold They are artificial, in other words The middle ear begins with the pharyngeal opening of the eustachian tube and ends with the most remote pneumatic space of the mastoid, all being covered by a membrane of unbroken continuity We may have these so-called superficial inflammations that do not involve the bone, but the covering of the bone, extending from the tube to the cavum, and even the mastoid cells themselves It is a rarity to find either an acute or chronic inflammation limiting itself to any one division of the middle ear It is in the epitympanic space that we behold the anatomic conditions which tend to perpetuate even simple inflammation, because of insufficient drainage conditions I refer to those innumerable little pockets in the epitympanic space formed by the various ligaments that attach the malleus and incus to the surroundings, all covered with mucosa For a long time undrained, infectious material causes the mucosa to take on the usual inflammatory changes, causing a discharge which resembles that from pure tubal disease In a large majority of these cases the perforations will be anterior or posterior to the manubrium, and in the pars tensa

How are we to get at these little pockets? The best way is by irrigation through the eustachian tube and through the opening in the pars tensa This can be done by means of the epitympanic cannula It can be done through the tube itself by the Weber-Liel catheter, a catheter made of woven silk, which is introduced through the eustachian catheter to the cavum, or to the isthmus, and the fluid forced in through the epitympanic space by means of a syringe I do not hesitate to do this I believe in these chronic cases the danger of forcing infectious material into the antrum is more or less, preferably more, fallacious

Here comes in the use of the boric acid and the dry gauze drain There was a war preceding the present war in Europe by some years, between the various camps in Germany, Munich and Halle being the respective citadels, and it became almost as deadly as the present conflict, one camp standing for the irrigation of the ear and battling against the dry method, the other upholding the standard of the dry and bitterly militating against the wet method Now we all know that irrigation has its place It has its place to remove debris, to remove secretions But we should be very careful how much we irrigate the ears in chronic otitis media suppurativa There is no doubt that there are cases in which injudicious irrigation only perpetuates the discharge, but when we find that this is true, all we have to do it to use either a boric acid pack or a dry gauze drain The dry gauze drain that I prefer is one made from xeroform gauze, one-half inch wide, packed against the perforation in the tympanic membrane, not pressing it, but in contact with it, and changed as often as this drain becomes moist Or the boric acid will produce results in cases in which the dry gauze drain will not, and this is especially so in cases in which the promontory of the cavum is largely exposed, in which perhaps the malleus handle has become necrotic and disappeared, and in which the mucoperiosteum of the promontory is granular In these cases, if the dry gauze drain does not produce dryness or a decrease of secretions, the head is bent to one side and the whole external auditory canal is tamped with boracic acid This can be done, of course, only in cases in which the perforation in the tympanic membrane is large

Granulation tissue in the cavum, projecting as a polyp through a perforation above or below the short process of the malleus or covering the promontory as a sodden mass, means that profound changes in the circulation of the mucoperiosteum have taken place, and that therefore the bone beneath has become more or less involved This should be removed by snare or cautery (chromic acid, iron perchlorid, trichloracetic acid), with proper precautions Alcohol, with or without salicylic acid or boric acid, is a most useful application in this class of cases, as well as in small cholesteatomas of Prussak's space

Now we come to the cases in which the mastoid is involved, and these are cases in which the bone must be taken into consideration Here we may have perforations in the pars tensa, or most frequently in Shrapnell's membrane, these are usually situated at the periphery of the tympanic membrane These are usually cases of cholesteatoma produced by the overgrowing of the epithelium from the auditory canal into the epitympanic space, which causes pressure, and this pressure causes destruction of the bone within the antrum and mastoid This is not a condition which necessarily demands operation It is our duty to ascertain the extent of the disease I have cured numerous cases of this kind, when small and not too old, by the use of the epitympanic cannula and alcohol This epitympanic cannula is inserted through the perforation of the epitympanic space, or in case there is a fistula, posterior or anterior, and that is washed out, and frequently I wash out large masses of cholesteatoma After this I either pack with boracic acid or dry gauze

How do we know the mastoid is involved? By the history of the patient, as to whether there have been symptoms of spontaneous pain or tenderness on pressure, of swelling back of the mastoid at the beginning of the otitis media, as to whether the discharge produced is purulent, as to whether the perforation is situated in the pars tensa or pars flaccida, by the skiagraph, by the recovery of cholesteatomatous tissue from the washings, by the presence of cholesterin crystals and bone plaques in the centrifugalized pus, by the presence of symptoms indicating meningeal or labyrinthine irritation Certain groupings of these symptoms indicate radical operative procedures, but this subject cannot be even touched on in this paper

I have just two more points first, as to suction That has been tried a great deal Personally, I have seen very little good come from it I do not believe, however, that it does harm or that it may be dangerous It should certainly be tried if any one would like to try it In one sphere it is especially useful, and that is in diagnosis as to the region whence comes the pus

Second, as to vaccines I have seen only one kind of case of chronic suppurative inflammation in the middle ear benefited by vaccines, and that was a case in which the epitympanic space was involved, characterized by a considerable discharge of mucus, and here we have found in two cases a pure culture, in one the staphylococcus, and in the other staphylococcus greatly in excess of the other kinds of bacteria Here the autogenous vaccine produced a cure in a little over two weeks in one patient who had been under treatment for as many months

22 East Washington Street

THE END-RESULTS OF TREATMENT OF CHRONIC SUPPURATIVE OTITIS MEDIA *

JOHN F BARNHILL, M D

INDIANAPOLIS

The end-results of treatment naturally fall under two heads, namely, the nonoperative and the operative

In nonoperative cases the results depend much on the correctness of the diagnosis In any case that is, in fact, a nonoperative one, the end-result should always be a cure of the discharge and improvement of function, provided the cause of the aural discharge is not a constitutional one, such as syphilis or tuberculosis, and there is no labyrinthic involvement present Many cases that are properly classified as nonoperative in so far as concerns the ear are, nevertheless, operative in the sense that the environment of the ear is bad, so bad indeed that operative measures for the improvement of nasal breathing are necessary In such as these the end-results of treatment depend much on surgical means for the removal of infectious foci of the nose, nasopharynx or pharynx

We may, therefore, dismiss the nonsurgical aural cases with the statement that when assured that any given one is actually in the nonsurgical class, cure should in the vast majority of cases be expected, and the hearing power should usually be improved

The end-results of the surgical treatment of chronic suppurative otitis media depend on many things

1 The age of the patient This, in my own experience, has had little to do with the outcome of surgical treatment, further than that the radical measures necessary to cure are somewhat more difficult in children than in adults, and the after-treatment usually cannot be so thorough with crying children as with older patients However, in cases of children in whom the aural disease or its treatment is not modified in any way by the conditions I shall shortly mention, I have found the end-results satisfactory in a high percentage of cases

2 The condition of the nose, nasopharynx and pharynx The end-results of surgical measures for the cure of chronic otorrhea are often failures to a great extent if the diseased environment of the ear is not corrected This fact is now generally accepted, I believe, by aural surgeons, for if, as believed, the nasal and nasopharyngeal diseases were the chief predisposing factor in the causation of the chronic aural affection, then cure of the aural disease must be unlikely so long as the diseased environment remains Clinical experience in the treatment of chronic running ears bears out entirely the correctness of this belief

3 The nature and violence of the original aural infection These probably more than any other factors determine the end-results of surgical treatment If the bacteria of invasion were violent of action, as is usually the case in the infectious diseases of childhood or in the severe epidemics of grip and as a result serious invasion of the osseous walls of the drum cavity or of the deeper portions of the adjacent mastoid or petrous parts of the temporal bone occurred, the nature of the final outcome may be in doubt, however, the end-result of surgical treatment will even then usually be a cure, but may possibly be only a partial cure and sometimes is a failure While of course the proportion of cures, partial cures and failures depends much on the conditions present in the patient, as set forth in the points of argument to follow, much depends on the skill of the surgeon at the time of the operation, and on his energy in following the case personally a sufficiently long time afterward

4 The presence of complications at the time surgical measures are attempted The end-results of surgical treatment of chronic aural affections, when complicated by extension of the infective processes to the labyrinth, meninges or lateral sinus, furnish a brilliant example of the progress and efficiency of aural surgery The end-result, of course, here depends very much on early diagnosis, since success in this class of surgery goes hand in hand with prompt diagnosis, which alone gives the surgeon his essential opportunity Increased knowledge on the part of the internist concerning the possibilities that may arise from a chronic aural discharge and the greatly increased facilities to early diagnosis of aural complications now at hand, when taken together with a better surgical knowledge on the part of the aurist than ever before existed, furnish the reason for the many brilliant cures that have been reported as a result of surgical measures for the relief

---

* Read before the Section on Laryngology Otology and Rhinology at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

of brain abscess and sinus thrombosis About 50 per cent of these patients are now cured, whereas formerly 1 per cent was regarded high The present percentage of cure will no doubt be raised when internists and others have greater solicitude for those patients who have chronic aural discharge Earlier diagnosis in a larger percentage of cases will then be made, and of course earlier operative opportunities will be presented

The weakest spot in surgical otology today is the end-result of meningitis, especially leptomeningitis, as a complication of suppurative otitis media, since practically all patients now die, whether operated on or not Some encouragement has been offered from operative methods and subdural drainage, especially by Crockett, who recently reported three cases of cure from this plan, but the majority of operators have not reported anything but failure The chief end-result at present, in so far as concerns meningitis, is prevention, and there can be no doubt but that all who operate for chronic suppurative otitis media according to the most approved technic frequently prevent this dangerous intracranial complication, hence it is evident that the end-results from treatment, especially the curative end-results, often depend on

5 The period of the disease in which the operative attempt to cure is made Largely, no doubt due to the facts that a chronic aural discharge is not often painful, and to the tradition that it may be helpful to the system, operative measures are not considered by the patient until danger signals have arisen which are clearly evident to the experienced aurist The nature of the end-results are often reversed by the delay, for results prove that radical mastoid surgery performed for the cure of a running ear, if done at a selected time, and before there is present any extension to some vital center, is among the safest surgical procedures, and also that when performed by those especially trained and experienced in this class of surgery, the cure of this discharge should be expected in the vast majority of such cases The end-results at present are therefore, not so good as they should be The fault lies with both the physician and patient The physician who should know the dangers resulting from delay should reeducate the public concerning the actual dangers due to prolonged aural suppuration Considerable knowledge about discharging ears existed centuries before disease of the appendix was known, yet today both physician and laity know vastly more of the diseases and dangers lurking about the appendix than about the equally common and equally dangerous chronic suppuration of the middle ear The only conclusion one can draw is that the abdominal surgeon has gone to greater pains to enlighten the public than has the otologist

6 The physical condition of the patient No argument is needed to prove that the end-result from the surgical treatment of chronic otorrhea depends much on the physical condition of the patient Conditions of ill health may be due to bad environment, overwork, undernourishment, chronic malaria, septic states due to the ear itself, or other foci of infection Most of these and others can usually be sufficiently overcome, in preliminary treatment, to insure a satisfactory end-result Likewise, when syphilitic, the condition of the patient may be so cleared that satisfactory aural treatment may be instituted Unfortunately, however, tuberculosis, either general or local, is often present in these cases, and the outcome usually is failure to cure

7 The skill and judgment of the operator While of course these attributes are necessary to the success of any class of surgery, they are especially essential in the performance of the bone surgery necessary to the cure of necrosing osseous tissue which lies in the midst of important and somewhat dangerous structures, the semicircular canals, facial nerve, lateral sinus and brain coverings Overoperating incurs great risk of injury to one or more of these structures, while timidity on the part of the surgeon is pretty certain to result in failure to cure, because of failure to remove all the disease

The nature of the end-result, whether cure or failure, frequently depends on the efficiency of the after-treatment of the patient following surgical means of cure The most satisfactory end-results are secured when the surgeon who operates gives personal attention to the after-care until the wound is dermatized, and healing is assured Failure is a not infrequent termination in patients, even though thoroughly well operated on, if afterward they are assigned to the care of physicians not especially trained in the management of this class of surgery I have the personal feeling that my work is only well begun when a radical mastoid operation is performed and that it is quite as much a duty to note the entire after-progress as to operate

The nature of the end-result often depends much on the patient himself, for sometimes as soon as he is able to leave the hospital, and when the external wound is healed, he acts on the belief that all has been done in the way of treatment that should be done, and therefore neglects to return for further observation or necessary care I have seen many examples of total failure due to such neglect following the most skilful operations On the other hand, I have observed many successful endings in cases that, during the first few weeks or even months following operative measures, were most unpromising, the final cure being obtained, I believe, by persistent, well-directed after-attention While the foregoing points determine in large measure the end-results of treatment, the results themselves may be considered

As to the effect on the hearing This, in the bona fide nonsurgical cases in which there is no labyrinthic involvement, is usually favorable, since there is frequently much improvement in function and seldom actual loss above that already present Following surgical treatment, especially following the radical mastoid operation, there has been, in my experience, usually a retention of the same degree of hearing as before the operation Occasionally I have observed some loss of function, and I think quite as often there has been slight gain Great improvement of function should not be expected as an end-result of surgical treatment The prime object of such treatment is to conserve life, and improvement of hearing should usually not be promised I am aware that a few American aurists make claim of almost invariable marked functional improvement following their own technic of operation, but I believe this claim is not made by the majority of aural surgeons

As to cure of the suppuration In strictly nonsurgical cases ultimate cure may be expected In patients operated on in a more or less radical way ultimate cessation of the discharge and dermatization of the operation wound will follow in 90 per cent of cases, provided the hospital facilities are modern in every respect, the surgeon is well experienced, and the after-care of the wound is given by one skilled in the healing of this class of wounds This estimate is, of course, exclusive of tuberculous cases

As to the mortality of the patient Nonsurgical aural discharge, while it remains nonsurgical in its nature, probably never ends disastrously to the patient When bone necrosis occurs, and when the case is therefore a surgical one, danger to the life of the patient is present in each case and at all periods of the progress of the disease Proper surgical treatment does not add to that danger, but on the contrary is the best-known means of avoiding a fatal result Radical surgery of the temporal bone, performed for the purpose of curing chronic aural discharge, is of itself remarkably free from danger to life In a record of about 300 radical mastoid operations I do not recall death in a single instance that could be attributed to the operation The real danger to life arises in neglected cases of chronic aural discharge, when the disease has already approached or actually attacked some vital spot The radical mastoid operation may therefore be regarded as especially free from danger to life in all cases in which it is employed before the meninges or sigmoid sinus has been attacked by the aural suppuration

Any discussion of the end-results of treatment of chronic aural suppuration would not be complete without mention of the fact that rarely the dura is uncovered accidentally during operative procedures, the sinus may be lacerated and the facial nerve may be exposed or severed Accidental exposure of the dura or penetration of the sigmoid sinus are of little or no consequence if the wound is left clean and the accidental injuries are properly dressed and managed Injury to the facial nerve is of course a serious accident, and one much regretted, but it should always be remembered that Nature, through the necrosing processes incident to the chronic otorrhea, produces many more facial palsies than does the experienced, careful surgeon-otologist

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS MACKENZIE, PIERCE AND BARNHILL

Dr Francis P Emerson, Boston Whether we have a chronic suppurative middle ear or an acute suppurative middle ear, the first essential is drainage through the membrani tympani, drainage which implies a sufficient opening, with the removal of granulations or anything that blocks the free flow of pus After that has been established certain primary conditions of the eustachian tube, dwelt on by Drs Pierce and Mackenzie, will have to be considered They are fundamental In a rational consideration of this subject we must have in mind some conception of the way in which this infection becomes chronic, and the methods which would be employed to clear it up One of the very early conditions is that connected with imperfect ventilation of the nasal pharynx, which is caused by the septum With a badly deflected septum there is either a compensatory hypertrophy of the middle or inferior turbinal This is followed by an increased function and hypertrophy The hypertrophy causes imperfect ventilation and imperfect drainage This latter is followed by a low grade infection which is constant and persistent and a source of reinfection of the eustachian tube A little later comes a more virulent infection, and this is followed by sinusitis Any preventive measure must take into consideration all of these factors—ventilation drainage, reinfection In certain cases of mastoiditis in children it is impossible to heal that mastoid until we remove the adenoids The primary cause of this middle ear trouble was an acute infection in the nasopharynx and because the connection is not more evident when these cases come to us as chronic cases does not imply that the primary focus is not still active Any conservative treatment must take into consideration the remedying of these conditions which cause reinfection These infections that have their focus in the sinuses extend to the epipharynx, to the eustachian tube, and later to the middle ear, so that a conservative treatment of the middle ear suppuration implies straightening of the septum and trimming the turbinals You must also cure the epipharyngitis, which is often a very active cause in keeping up an irritation in the tube

Another point is that the eustachian tube on the side of the middle ear which is most involved is always the one most open If you catheterize the eustachian tube you will find that to a certain extent it has lost its power of contraction and that the condition is often made worse by auto-inflation by the patients themselves

After you have relieved the primary foci and the resulting infection, and established drainage of the middle ear, many patients will get well without further treatment All the other measures that are applied directly to the middle ear come in as a part of the secondary treatment

Dr W Eugene Dixon, Oklahoma City I was very much interested in Dr Pierce's remarks on otitis media, especially on the tubal treatment, but I wonder how many here find difficulty in using the No 1 wire with cotton on the end passed through the catheter as a guide into the eustachian tube I cannot get through the isthmus of the tube as easily as the doctor says he can I want to present a technic for passing cotton wound applicators, bougies, electrodes or syringes into the eustachian tube by the direct method without using the catheter as a guide Wind the cotton very thinly, but securely, around the applicator from the tip to one-half inch above the bend Dip it into cocain, to cocainize the mucous membrane Into one nostril pass the Holmes nasopharyngoscope Adjust it so that the upper one half of the mouth of the tube is in plain view Into the other nostril pass the cotton wound applicator in such a way that the tip of the applicator is on the floor of the nose Looking into the scope you can see it as it emerges into the nasopharynx Carry it outward, and backward into the mouth of the tube in a vertical direction, and remembering the anatomy place the tip on or near the floor of the tube, rotate the applicator or syringe tip outward, upward and backward, all the time keeping the instrument after its rotation in the upper part of the tube, or between the anterior and posterior plates of the upper portion It is very easily done

Dr Cullen F Welty, San Francisco Dr Pierce said that chronic suppuration of the middle ear is easily treated and that a cure results in a majority of cases—if the proper treatment is given This is a most remarkable statement coming from a man so prominent I have tried for weeks and months to do the various procedures that have been described, with little or no results Patients come back in two or three weeks or months with a discharge from the ear again The number of patients cured by treatment as compared with the number cured by operative procedures, is almost infinitesimal Dr Pierce also says that he cures cholesteatoma by irrigating the middle ear which is absolutely ridiculous It cannot be done, as he well knows

He also says that if there is mastoid involvement, these patients are not so likely to get well How do you know whether there is mastoid involvement? He says If there has been pain or tenderness back of the ear I challenge anybody who makes such a statement as that People may know whether they have had pain or tenderness back of the ear, but you cannot say there is mastoid involvement because of any such symptoms, as the pain and tenderness may be produced by tooth root abscess—imbedded teeth or a buried tonsil I have had to contend with all these and many more I wish to say furthermore, that in the radical mastoid operation a large percentage—90 per cent—of the cases have large lesions within the mastoid cells, lesions that could be seen at from 10 to 15 feet If we are confronted with such statements as Dr Pierce has made, somebody must have the courage of his convictions and get up and explain why this is not just as stated Dr Pierce speaks of tuberculosis—that these patients do not get well so what is the use of operating? The only treatment for a tuberculous ear is to operate thoroughly, and if you operate thoroughly you will cure them I have such cases on record

Dr Emmett L Jones, Cumberland, Md For many years I have treated my patients by a simple method which I described two years ago I believe all ear infections originate in or travel through the rhinopharynx, and if we are to treat them successfully we must begin with the rhinopharynx If we do that we will have nearly 100 cures in 100 cases With this method the hearing is always restored, the perforations heal, the discharge ceases, and there are no mastoid symptoms Patients who have had for several days purulent mastoid symptoms according to all accepted standards, following this treatment get well, and even some chronic cases are cured The basis of the treatment is the daily application to the rhinopharynx of a strong solution of phenol (carbolic acid), tincture of iodin and glycerin, from which you have the reaction of a bad sore throat Then in acute cases I dip the tip of a tampon in a solution of epinephrin in anilin, 1 1,000, with 10 per cent of cocain added, and apply that frequently to the drum membrane In a few hours the pain eases, the discharge soon amounts to nothing, and the trouble in the mastoid gets well, and there is absolute restoration of hearing

Dr J Holinger, Chicago The main part of Dr Beck's paper is his pathology Pathology of chronic suppuration of the middle-ear has not been given, and therefore we will not and cannot come to an agreement on how to treat it If we have a carefully worked out pathology, the indications will become evident, and then we might agree, but this way we cannot

Dr A E Prince, Springfield, Ill I want to direct attention to a simple method of securing a partial vacuum in cases of incipient mastoiditis Every acute inflammation of the middle-ear should be considered in its relation to the antrum and mastoid cells which are usually involved The establishment of a partial vacuum in a large percentage of acute cases, and in some subsequent cases, will prevent the extension of the disease and bring about a cure Dr Baum carried through a series of cases which were recommended for mastoid operation, by the use of Bier's vacuum method, and cured 80 per cent without an operation The method I recommend is much simpler It consists of instructing a mother or nurse to use the flaring end of a soft catheter which is selected to fit the external meatus By sucking with the mouth at frequent intervals the patient is relieved, and the disease is prevented from extending to the deeper cells, an operation is avoided in a considerable number of cases If the patient be mature he can do this himself He will know when it hurts and avoid excessive suction This is applicable after every paracentesis and every spontaneous rupture of the drum membrane It does not apply to cases of chronic suppuration, but to recent cases

Dr Oliver Tydings, Chicago The causes which brought into existence suppurative otitis media, if left uncorrected, are sufficient to keep it going to the end of time I wish to endorse the tube introduced by Dr Prince I have used that treatment for a number of years It was not original with me, I do not know where it came from I am sorry to disagree with Dr Pierce on cholesteatoma I believe that cholesteatoma has a separate and distinct etiology—and this in spite of no less an authority than Politzer My own experience is at variance with his, and proves conclusively to my mind that it is due to a separate and distinct entity from the cause of suppurative otitis media, and must be treated by separate and distinct methods of treatment I have used the same catheter Dr Pierce used, I have washed out the tympanic cavity until I was tired and the patient's endurance exhausted—and although I have not reached the degree of efficiency in the use of the catheter that Dr Pierce has—and while I was doing that work patiently, and sometimes had an erosion of the semicircular canal with the resulting disturbance of equilibrium, showing that with all my washing, I still got enough accumulation there to appall me, so I quit washing out and I have not washed an ear for this malady for some time The only thing I do or advise for cholesteatoma is to operate, and the sooner done the better In regard to vaccines I have found them useful in some cases and have gotten some very beautiful results with the mixed vaccine

Dr Harry B Harris, Dayton, Ohio It strikes me that Dr Dixon's applicators are too stiff to pass through the eustachian tube without doing injury The applicators I am using and have used in several hundreds of cases are those of Dr Yankauer I do not recall any case in which I was unable to pass the applicator through the isthmus and make my application as desired These applicators are made of very delicate wire, bent back and twisted on itself which makes it double, leaving a very small loop at the end where the cotton is applied It is impossible for the cotton to come off of this end if properly put on, and the applicators are so flexible that they easily mold themselves to the shape of the tube without undue force

Dr W Eugene Dixon, Oklahoma City I have been using these applicators since 1910, and never once in that length of time has the cotton come off The cotton is wound not only on the end, but clear back of the bend and therefore it is always in sight If it did come off all you would have to do would be to pull it out with a pair of forceps through the nose, as the bend of the instrument which is covered with cotton is not in the eustachian tube and therefore the cotton would be left hanging in the nasopharynx The new applicators are threaded on the end for some distance which holds the cotton very securely, in fact so secure that it is very difficult to remove it after the use of the applicator As far as injuring the tube is concerned, the cotton wound applicator can be passed just as gently as a catheter can be passed into the urethra It is held in one hand and passed while with the other you hold the nasopharyngoscope, and see just what you are doing in every step of the operation The sense of touch is acute and one can very readily develop a technic without doing harm

Dr William S Tomlin, Indianapolis As to tuberculosis of the middle ear, having had some experience as consultant in the treatment of tuberculosis for a sanatorium, a considerable number of patients have come under my care Of most importance in their treatment is the local application of tuberculin emulsion We start usually with the dilution No 1 or No 2, and gradually increase it Our experience has been very favorable in the local treatment of these cases where the opening into the drum was sufficiently large to make a successful application In some cases I have tried to introduce it through the eustachian tube, but that has not been successful when the opening into the drum was not large These cases require especial attention when tuberculosis develops in the throat Tubercular infection of the middle ear may be said to be almost always derived by way of the eustachian tube I am also of the opinion that the primary causes which have influenced the development of infection of the middle ear must be removed if we expect them to recover with nonoperative treatment, and in many cases even with operative treatment the ear will continue moist, giving rise to recurrences, if you do not remove the cause In some cases in which I have not been able to find adenoids, teeth, infected tonsils or indications of the source of infection, the treatment of the lower end of the eustachian tube has brought about results In these cases I have found the patients would state that they had noticed when attempting to blow the nose in the ordinary way, without any extraordinary force, they would constantly hear the blowing of the air into the middle ear

Dr Charles M Robertson, Chicago I have been waiting to hear some one raise the point of diagnosis of perforation of the tympanic membrane In chronic suppuration of the middle ear if the discharge consists of mucus from the eustachian tube, there is no use putting on suction, there is no use putting medicine in the ear, there is no use in lavage If the patient wishes to clear the tube he can do it by blowing the air through from the pharynx In case of suppurative disease of the ear per se, if the discharge is coming down from the attic, there is no use to wash by cannula as the case requires operative treatment In regard to perforations, we divide them into innocent and dangerous If it is a dangerous perforation there is no use in trying anything else but an operation When the opening in the drum membrane is large anteriorly and of innocent type the case is usually tubal and the tube should be destroyed With the perforation in Shrapnell's membrane, there is no use to expect results by topical treatment, the opening should be enlarged to promote drainage and if this is not sufficient to produce cessation of discharge the patient should be operated on by a complete exenteration I use the gauze treatment in the last part of a suppurative discharge in acute cases and it has done very well in suppurations of this type In all of these chronic cases a radical mastoid operation should be performed

Dr **Clark W Hawley**, Chicago I do not know how to treat suppurating ears This man says do this, and that one says do that I say it depends on the symptoms in each case In acute suppurating ears do not use water I use absolutely no water, I have not washed a suppurating ear for twenty years I simply put a piece of cotton on a small toothpick and pass that into the ear until I get it clean

Dr **George W Mackenzie**, Philadelphia We should anticipate complications before they arise In the first place, any acute middle ear suppuration which endures for more than six weeks is complicated There is something that is delaying recovery, and it is for us with what knowledge we possess of the pathology of middle ear suppuration to determine what is at fault and whether there is a single factor or multiple factors By a thorough examination one is often made aware of complications before the patient complains of symptoms suggesting them Nine or ten years ago I examined a series of 117 cases of cholesteatoma They were examined before operation and a diagnosis of cholesteatoma was made in every case by a microscopic examination of the washings from the ears The results of these examinations were published The secretion of little flaky particles that come out of the ear when washed is put under the microscope in its natural state and examined for micro-organisms and crystals The crystals are rhomboidal in shape, many with a corner broken off When cholesterin crystals are found, the patient has a cholesteatoma In 117 cases in which radical operation was performed, the diagnosis made by the microscope prior to operation, was substantiated Furthermore, there was not a single case of cholesteatoma that had not one or more complications, which, I think, is the strongest argument in favor of operating in all cases of cholesteatoma We run too much risk by trusting to conservative methods

Dr **Norval H Pierce**, Chicago My brief remarks were for the purpose of calling attention to my views regarding chronic suppurative otitis media, and I endeavored to show that chronic suppurative otitis media is not a simple matter It is not an entity A discharge from the ear is only a symptom of a very complicated pathology involving a very complicated organ I think I do as many radical mastoid operations as any gentleman present I do not hesitate to do a radical mastoid operation But I think that the man who on seeing a chronic discharge from the ear says that the only possible treatment for it is a radical mastoid operation is devoid of proper education or is a fanatic I regard cholesteatoma as it involves the ear as a very dangerous condition, one that most frequently calls for proper radical treatment I have cured cholesteatomatous conditions of the middle ear by other means than the radical operation, and have retained for the patient a sound conducting apparatus that has a very much better function than the sound conducting apparatus of a patient who has been operated by the radical method after four or five years I am not disparaging radical work I am hoping that you will not regard the suppurative ear as an indication, and unequivocal indication, for radical work Dr Dixon drew attention to his applicators for the eustachian tube The eustachian tube is not a straight tube, it is a tube that has more or less of an angle at the isthmus, and I cannot see how he can drive that straight inflexible staff up a tube that has an acute angle. That is the reason I use a very flexible silver applicator There are tubes through which we cannot push even this very flexible applicator because of the acuteness of the tubal angle. Regarding the strictures of the tube, Schwartzen a very long time ago investigated on the dead body the frequency with which organic strictures of the tube occur, and his report was to the effect that in simple inflammatory conditions, strictures of the tube practically never occurred They occur as the result of diphtheria, syphilis, and some other diseases, but then the strictures are situated at the pharyngeal end of the tube, and according to his report there was never a stricture at the isthmus The reason men think the tube is very frequently the site of stricture is because the probe, or bougie, or applicator is arrested at the acute angle I am sorry to think that any gentleman in this section would criticize a remark that I might make here as absurd and ridiculous I have given this question of otology the best part of my life I have tried to analyze cases, having ample opportunity and material to reach certain conclusions, and I say now, that if we do not treat these chronic suppurative inflammations in an intelligent manner, if we resort immediately to the destructive—because it is destructive—radical procedure, if we do not attempt to bring about a cure in these cases that present no symptoms of rapid advancement of cerebral or other complications, then we are not doing our duty to our patients and are undoubtedly rendering ourselves liable to the very ignominious appellation of plain, ordinary, common or garden variety of butcher

Dr **John F Barnhill**, Indianapolis Some remarks were made that it seems to me ought to be corrected The question is the problem we must meet in the chronic discharging ear Each patient is a problem If the problem is a simple one, if, as Dr Pierce has said, the whole trouble is in the eustachian tube, clearly the problem is one of the eustachian tube and not of a mastoid operation If the trouble is in the environment of the ear, if there is a bad state of ventilation, if it is the epipharynx that is involved, then the problem should be attacked from that angle One gentleman says 100 per cent of his patients were cured by his treatment of the epipharynx I believe these were acute cases and therefore do not fall within the line of our discussion I think every one recognizes the value ordinarily, of treatment of the epipharynx, but to allow a statement such as Dr Jones made, that 100 per cent of patients were cured by this treatment, to go unchallenged, would be wrong Now I think we have seen cases in which we have not had any time to make any application to the nasopharynx There is often a mastoiditis almost as soon as there is a middle-ear disease, and it does not stand to reason that we could cure that kind of mastoiditis by local application to the nasopharynx If there is necrosed bone, and if reasonable local treatment has been given, I think Dr Pierce will agree with me that if the suppuration continues some kind of surgery is necessary, and that radical mastoid surgery is best If there is cholesteatoma present, I think that not 95 per cent but 99 per cent of these cases are cases for the radical mastoid operation So many of them are complicated Suppuration from the ear means that something is rotting Pus is the product of decay, and if something is decaying and the decay continues long enough it will get into the meninges, the sinuses and the labyrinth, or some other dangerous place It is not wise to stand by indefinitely and allow a chronic suppuration to go on without warning our patients that an operation, after reasonable treatment, is the best and safest procedure

Dr **J Holinger**, Chicago I should like to caution against the use of anilin I have seen serious symptoms of poisoning develop after a few drops of the oil were poured in the ear It was a case of acute otitis media without perforation, and while it was not fatal, it kept me in hot water for a whole night I never shall use anilin in the ear under any condition

---

The Anesthetist—The surgeon is greatly dependent on the anesthetist The risks of anesthesia should not be disregarded, and will not be underestimated by any one who has encountered fatal idiosyncrasies in patients In a difficult case the skill of the anesthetist may be of no less importance than that of the surgeon himself—S S Goldwater, M D, *Modern Hospital*, November, 1916

WOUNDS IN WAR AND METHODS OF TREATMENT

A U DESJARDINS, M D
Formerly Assistant Surgeon American Ambulance Neuilly and First Assistant Surgeon, Hopital Complementaire, V R 76, Ris Orangis France
WATERVILLE, MAINE

Before the wounds produced by modern military projectiles as seen in the present war are described, and before the methods which have been found most efficient in dealing with them are discussed, a brief consideration of how these injuries are inflicted and especially of the conditions under which they are received may not be out of place, because those conditions have an important bearing on the character of the wounds and on their treatment As Surgeon-General Sir Anthony Bowlby[1] has stated, "one of the most important points for present consideration in connection with the wounds of war is the geographical situation of the battlefield"

During the first five or six weeks of the war the fighting was in the open, but, since the battle of the Marne, with a few exceptions the contending forces have lived and fought in trenches The territory in which the fighting has been done is, or was before the war, a thickly populated and intensively cultivated region The soil, on the whole, is a rich loam, and for generations it has been heavily manured It produces abundant crops, and provides sustenance for large numbers of cattle Then, too, the climate is moist During the winter months, from late October until early April, it rains on about five out of seven days, and during the summer months there are many cloudy days Such conditions, as one might expect, are ideal for bacterial growth, and this soil teems with micro-organisms of every kind, including large numbers of spore-forming pathogenic anaerobes

The trenches are deep, and for long periods the soldiers have to stand or move about in mud and water to their ankles or even to their knees They have to sleep as best they can on the floor of the trench, on dirt shelves dug out of the trench, or in one of the scattered shelters made of rough timber, so that they are covered with dirt and mud from head to foot, especially during the winter

If a man in the trenches is hit and falls, he has to lie in the dirt, mud or water until assisted by comrades Every soldier is provided with an individual dressing which is immediately applied by himself, by a comrade or by stretcher bearers as dirty as himself One can imagine what such a dressing is If he is able to walk, he goes by a narrow communicating trench to the nearest *poste de secours* or dressing station located in an underground shelter or cellar, protected against shell fire, from several hundred feet to several hundred yards back If unable to walk, he must be carried, but the trenches are narrow and crooked, and render the use of an ordinary stretcher out of the question To overcome this difficulty, both French and English have devised an ingenious trench stretcher If a heavy bombardment or an attack is in progress, the wounded often have to lie for hours where they have dropped, until they can with some degree of safety either walk back to the dressing station or be picked up and carried by stretcher bearers During an attack on the enemy trenches it often happens that a wounded man has to lie in the open between the opposing trenches until nightfall affords him sufficient protection to crawl back to his own trenches, or permits a relief party to bring him in

In a large percentage of cases there is a considerable interval between the injury and the first dressing at the dressing station During the first month of the war many men remained on the field for a number of days before being picked up, and the results of such prolonged exposure to every factor favorable to infection would be impossible to describe The sudden necessity of defending their territory made it necessary for the French to utilize every means of transport to push their troops to meet the rapidly advancing enemy and to keep these troops supplied with food and ammunition Force of strenuous circumstances made the care of the wounded a secondary consideration During the first month of the war large numbers of French wounded fell into the hands of the Germans At the battle of the Marne, thousands of French wounded, after remaining on the field for several days in many cases, had to spend several hours more baking in freight or even open flat cars under a hot August sun on some railroad siding, their wounds in the meantime "stewing in their own juices," while trainload on trainload of troops was being sent forward to pursue the fleeing Teutons By October, 1914, however, this state of affairs had considerably improved, and has been steadily improving ever since, until now the wounded are evacuated and cared for as quickly and as efficiently as can possibly be done with due consideration to the character of the fighting and the difficulties it presents And these difficulties are great

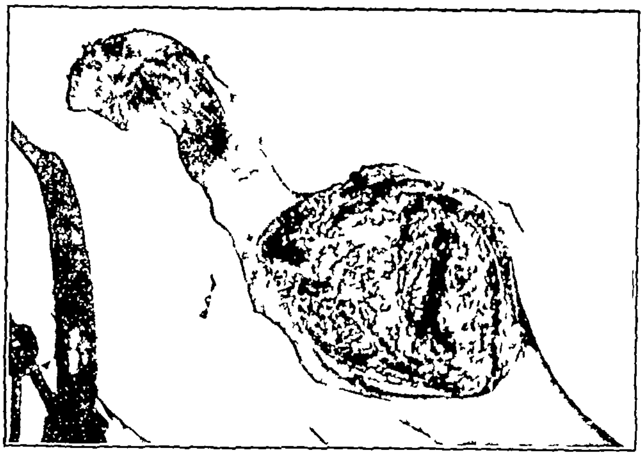

Fig 1—High explosive shell wound of right shoulder with destruction of deltoid and shattering of upper third of right humerus (Photograph by King—American Ambulance)

During the open fighting which characterized the first weeks of the war, the French armies, obliged to retreat before the vastly superior numbers of the Germans, could not establish any but temporary field hospitals The best which could be done at that time was to put the wounded on cars and send them back to base hospitals in Paris and the provinces to the south But after the battle of the Marne had forced the Germans to "dig themselves in" and the Allies to imitate them, it became possible to establish at short distances behind the lines temporary field ambulances,[2] which were gradually organized so that urgent operations could be done We must remember that all these dressing stations and field ambulances are within artillery range Sometimes field ambulances are located in buildings partly demolished by previous bombardments, sometimes in a cellar, others again are located, as in the Vosges and Argonne districts, in underground chambers dug out of the side of a hill and carefully concealed and protected against shell fire The equipment of these ambulances depends to a large extent on the resourcefulness and ingenuity of the surgeon in charge In spite of tremendous difficulties, however many of these field hospitals are equipped with every essential to the performance of all kinds of major surgery

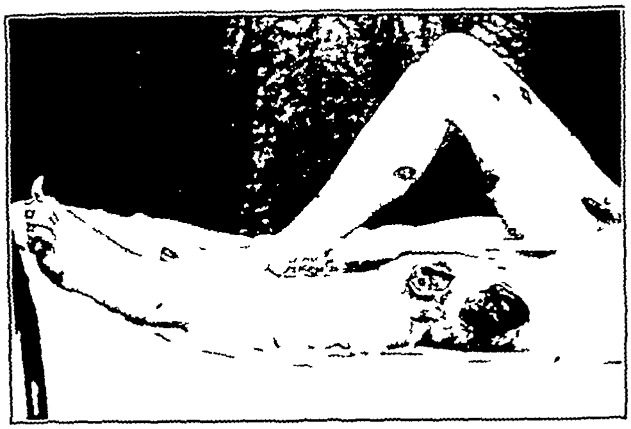

Fig 2—Multiple shell wounds of both lower extremities with purulent arthritis of left knee Photograph taken on admission Bridge plaster cast applied at evacuation hospital (Courtesy of the American Ambulance)

To give an idea of the difficulties with which they have to contend, a French surgeon in charge of a field hospital of 2,000 beds behind the Somme front told me not long ago that, in one period of thirty-six hours, 600 wounded had passed through his own hands He had worked out a new splint for fractures of the femur, but with such a rush of the work he had been able to apply it in only a few cases and had not been able to follow its results, because the wounded had to be evacuated immediately to make room for fresh arrivals This impossibility of following cases and seeing the final results of their work is one of the most serious handicaps of field ambulance surgeons But war is war, and a field hospital must always be ready to receive and quickly care for the newly wounded and keep itself cleared by evacuating them as soon as possible to the base hospitals by way of the intermediate evacuation hospitals This will explain why it is that the best ground on which to study the wounds of the war and the different infections and complications which so frequently accompany them is the base hospital because here cases can be followed, and the results of any line of treatment can be controlled by daily observation Another surgeon, working behind the Verdun front, told me that in one week he and his associate had performed 400 operations in an underground ambulance and under shell fire much of the time Under such circumstances errors of judgment are to be expected, and technic must be boiled down to the bare essentials

At the dressing station the wounds are given their first real dressing by a surgeon, who may have had antebellum surgical experience, or who, previous to the war, may have been a general practitioner or a recent hospital intern No operations are performed at the dressing stations The wounds are examined, quickly dressed with a view both to the cleanliness of the wound and to the comfort of the patient, and the men sent back, on foot if they can walk, or on a stretcher suspended from a two-wheeled cart pushed or pulled by two men, or sometimes in a horse-drawn ambulance, to the nearest field hospital Here they are given one or more doses of tetanus antitoxin, their wounds are explored and drained, accessible foreign bodies are removed, fractures are temporarily splinted, and all patients in condition to be transported are then sent by motor ambulances to the nearest evacuation hospital In very serious cases the patients may be kept at the field hospital until their condition warrants transportation At the evacuation hospital, for instance at Bar le Duc or at Revigny for the Verdun front, or at Amiens for the French part of the Somme front, they may be kept for a few hours to several weeks depending on their condition, the intensity of the fighting going on at that portion of the front, and the numbers of wounded requiring attention Here wounds are more thoroughly drained, fractures are put into more permanent splints for treatment or for transportation, and the men are then sent on by train to the base hospitals in Paris or in other provincial cities By the time they reach the base hospital, therefore, they have as a rule had more or less treatment, although during periods of heavy fighting it occasionally happens that some men reach the base twenty-four, thirty-six or forty-eight hours from the time they have been wounded, and with the original dressing applied at the dressing station still undisturbed The average time between the wound and the arrival at the base hospital is about two weeks

PROJECTILES AND WOUNDS

It is impossible at this time to estimate the proportion of wounds caused by bullet, shell, shrapnel, bayonet, bomb or grenade During the first weeks of open fighting leading to and including the battle of the Marne, the number of bullet wounds was relatively high Since that time, however, a large proportion of the wounds have been caused by shell, shrapnel, bomb or grenade Bayonet wounds are rarely seen except in the immediate zone of fighting, because such injuries, being inflicted at close quarters, the long blade generally penetrating the abdomen or the chest, usually mean instant or early death. Men so wounded seldom live to reach a base hospital.

---

[2] 'Ambulance' is a name given in France to a temporary military hospital to distinguish it from a permanent military hospital

The construction and ballistics of the different types of projectiles have been amply described and explained by others. I shall limit myself, therefore, to those features which are peculiar to this war.

The effect of the pointed rifle bullet depends largely on the distance from which it has been fired. The proximity of the opposing trenches accounts for the frequency of the explosive effects observed in many cases. During the early stage of the war such results led to charges that the Germans were using dumdum bullets. There may have been isolated instances in which a soldier turned the bullet rear end forward in order to inflict more damage, but this is not at all necessary to explain the explosive effects which Reverdin of Geneva has found to be due to the violent impact of the bullet on a fluid-containing object or tissue.

The impact of one of these bullets on a large bone especially at short range, causes extensive shattering, and the fragments are driven with great force into or through the surrounding soft parts with resulting wide rents of skin and fascia and extrusion of muscle. Rarely one encounters a clean perforation of a bone without fracture or with only a fissured fracture. Almost invariably, however, bullet fractures are badly comminuted.

Shells are largely of two kinds, shrapnel or high explosive, and on account of the greater effectiveness and destructive power of the latter, more and more of this type are being used. The effective range of the shrapnel shell is not very great, because the balls rapidly lose their initial velocity. The wounds they produce are not as bad as the worst of those inflicted by the ordinary rifle or machine gun bullet, but, being easily deformed, in some cases they are responsible for considerable damage. On the whole, however, their destructive power is not very great.

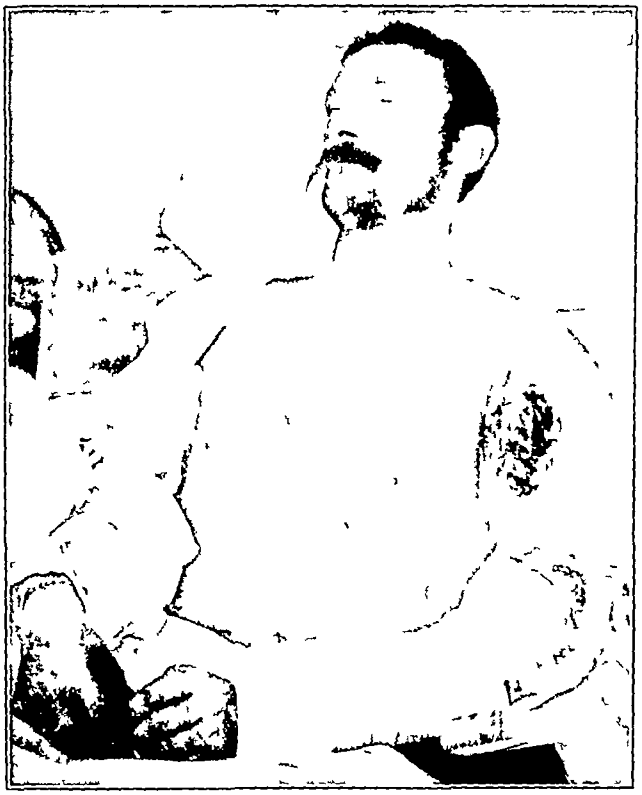

Fig. 4.—Perforating shell wound of upper left arm with compound comminuted and badly infected fracture of left humerus. (Photograph by King—American Ambulance.)

Of all the projectiles, none produces such frightful or extensive wounds as the high explosive shell, which in bursting projects with intense violence innumerable jagged fragments of every size from that of a grain of sand to pieces as big as one's hand. And the size of the piece may bear no relation whatever to the size of the wound. The sharp, irregular edges tear skin, fascia and muscle, and pulpify nerves and vessels, causing widespread crushing, contusion, extravasation of blood and sloughing of large areas. One of the worst features of such wounds is that these fragments of shell tear off pieces of clothing, which are carried into the deepest portions of the wound, so that it is extremely common, even in superficial wounds, to find their edges and raw surface covered with shreds of clothing. In deep wounds with widespread laceration of tissues, such pieces of clothing, covered as they are with the dirt of months in the trenches, find favorable lodging in recesses filled with extravasated blood, and are responsible for much infection. Even if a soldier is not actually struck by one of these fragments, the force of the explosion as the shell strikes the ground may project stones, sand and mud, and thus produce wounds which may be very serious. I well remember one man who had been wounded at Douamont, near Verdun. His right thigh showed three deep, penetrating wounds which, when incised and explored, were found to contain a small handful of stones. In another man I recall taking out several pieces of wood which had been driven into an ugly wound of the buttock.

The sudden violent explosion of one of these shells, especially those of large caliber, causes such an atmospheric disturbance in its immediate neighborhood as sometimes to produce death without any external wounds. In some of these cases there has been found a rupture of one or both lungs; in others nothing could be found beyond numerous petechial hemorrhages of the brain.

Bombs, grenades and torpedoes are of many kinds. They essentially consist of a container of iron or some other metal filled with a variable charge of high explosive powder, and are particularly vicious because they explode in the trenches, within a confined space, often producing multiple nasty wounds which, like the shell wounds, are always badly infected by the dirt, mud or clothing introduced by the fragments. These fragments are usually small, however, and as they quickly lose their velocity, do not generally produce the extensive ravages encountered in shell wounds.

In all these injuries the effects are not limited to the immediate wound tract, but may be spread over a wide area, and on microscopic examination pathologic tissue changes may be found "at a considerable distance from the site of the obvious injury."[1]

COMPLICATING FACTORS

By far the most serious complicating factor is the general infection of all the wounds. We have already studied the conditions that lead to this infection, which is always of a very mixed character, although in some cases one organism or another may predominate.

Tetanus and gas infection, while still occasionally encountered, are not nearly so prevalent now as they were in the fall of 1914 This dreaded gas infection, so rare in ordinary civil practice, has been and still is one of the problems of the surgery of this war

GAS INFECTION

The infection is due to the introduction into the tissues of gas-forming anaerobic organisms, chiefly the *Bacillus aerogenes-capsulatus* of Welch, known in France as the *Bacillus perfringens* Cultures made from a long series of wounds at an early stage show its presence, usually in conjunction with pyogenic organisms, in a large proportion Fortunately, in most of the wounds the tissues are so widely ripped open as not to provide the anaerobic conditions necessary for the growth and activity of the organisms, because in a large percentage of cases they disappear in a short time In a few cases, however, while the gas formation may be limited to the injured part the infection may be so intense as to overwhelm the patient in a few hours The type of wound in which the rapidly spreading form of the infection is generally seen is the deep wound in which the projectile, instead of widely tearing the muscles apart, has split fascia and muscle, and lodged, often after injuring the vessels, in some muscle mass, as in the calf, thigh or arm The majority of the cases seen were in deep wounds of the thigh

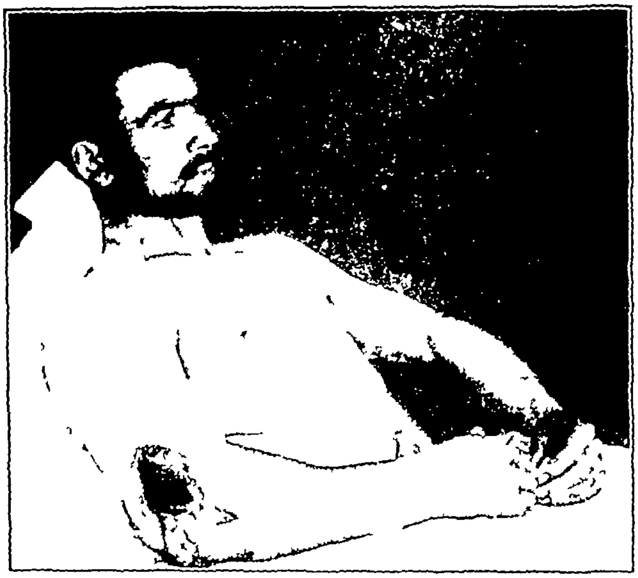

Fig 5 —Gas infection of right arm with shell wound of lower arm Note distention of arm and edema of hand (Courtesy of Dr Joseph A Blake)

To give an idea of the appearances and behavior of gas infection, I shall take an actual case and for the sake of science, allow the condition to follow its natural course

A French soldier was brought in during the night let us say having been wounded in the right thigh four days previously by a piece of shell He has had only one or possibly two dressings On entering the ward in the morning and approaching the new patient's bed one may be struck by an odor which is something between fresh manure and ancient eggs The temperature may be anything between 99 and 101 or 102 and the pulse from 100 to 120 The patient is restless and complains of considerable pain about his thigh When the dressing is removed the first thing to attract one's attention is the distention of the thigh it may be twice its normal size Areas of bluish or purplish discoloration and sometimes a number of blebs may be apparent in the region of the wound On palpation the skin is tense and on gentle pressure a distinct crepitation may be felt On examination of the wound the skin will be found split or torn apart, and a mass of dry, grayish brown muscle protruding If the dead muscle is spread about the wound tract or a probe passed into it, a thick, muddy brown pus will exude, and if pressure is made on the tissues about the wound, bubbles will be seen in the discharge or even on the muscle surface The odor from the wound is quite characteristic Aside from the restlessness, the patient may not look very ill and one may be easily deceived When first seen at 8 o'clock, the crepitation extended up to the groin At noon the crepitation may have reached the umbilicus The discoloration has increased At 3 o'clock the crepitation may extend to the pectoral region By 9 o'clock the gas has begun to raise the skin of the neck and the local signs at the thigh have increased In the wound the protruding muscle is quite dead dry and brittle except along the tract of the missile, which is covered with a dirty muddy brown discharge mixed with bubbles of gas At midnight the patient is more restless, the temperature may have gone down but the pulse has begun to flicker The neck is now well distended and crepitating At 3 in the morning the eyelids begin to look puffy, and the patient begins to complain of difficulty with his respiration The gas has invaded the tissues about the throat and as it increases, the respiration gradually becomes stertorous The patient who, until now, has shown a clear mind, begins to wander and by 9 o'clock he is dead

This is about the course of rapidly spreading gas infection, but in some cases neither the onset nor the progress of the condition is so rapid Furthermore, as already stated, only a small proportion of the wounds infected with gas-forming anaerobes follow such a course

Taylor[3] has shown that the pathology of gas infection consists essentially of a widespread degeneration of the muscle fibers subjected to the increasing pressure of the gas resulting from the activity of the anaerobes which find an ideal medium in masses of

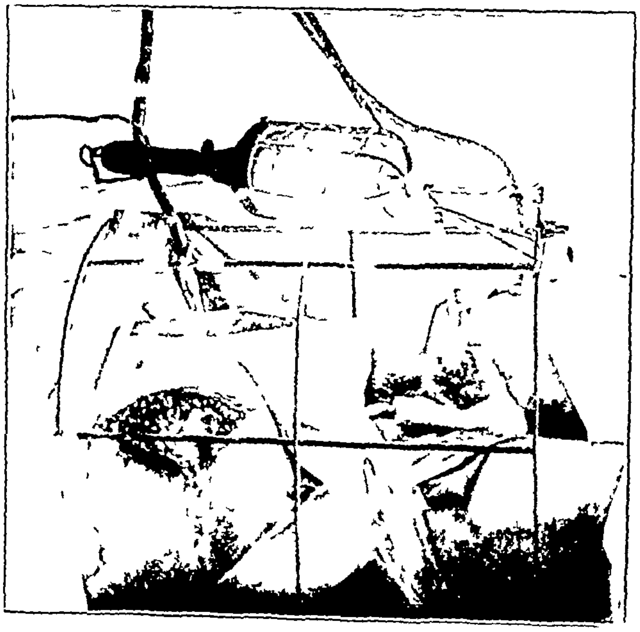

Fig 6 —Superficial shell wounds of abdomen and scrotum with bilateral testicular hernia treated with Dakin solution and electric light Note erosion of skin of right side by solution (Photograph by the author)

contused and devitalized muscle, especially when the main blood vessels of the limb have also been involved in the injury. This is followed by rapid systemic intoxication and septicemia.

METHODS OF TREATMENT

In the surgery of civil life an injury is not usually exposed to so many evil influences, and the prompt attention it receives has much to do with the comparatively uneventful recovery of the patient. If a soldier could keep relatively clean, and if, when wounded, he could be immediately taken to a well-equipped hospital and cared for, instead of having to be left lying for hours in dirt and mud with one or more wounds filled with dirty clothing, dead tissue, extravasated blood, and one or more foreign bodies, we might expect a better course and a more rapid recovery, and reconstructive surgical procedures could be employed sooner with shortening of disability.

Much has been written about the treatment of wounds, especially in Europe, since the war has given such an importance to the subject. The first great problem, since it is impossible to prevent the infection of these wounds, has been how to combat this infection. It was early recognized that one important step in the right direction was an early and thorough exploration and cleansing of the wounds. It was for this purpose that both the French and the English took advantage of the comparatively stationary position of their armies to establish immediately behind their lines field hospitals in which the wounds could receive the earliest possible attention. This measure alone has been the means of saving thousands of men. In the cases with abdominal wounds, for instance, it has been shown that the mortality depended absolutely on the time between the reception of the injury and the operation. Unfortunately, the range of usefulness of these field hospitals has necessarily been somewhat restricted by the very conditions under which the work has to be done.

And now we come to another great problem, and that is the use of antiseptics in an effort to bring about rapid sterilization and healing. If I may again quote Sir Anthony Bowlby:[1]

> It is at this stage that we find two different schools of thought amongst those who are not at the front as to what is best to be done in the treatment of the wound. One school, which draws its experience mainly from the surgery of civil life, would persuade us that all our wounds, if properly treated, should be completely sterilized—at a single dressing if seen early enough—by the application of this or that antiseptic agent, and in any subsequently septic wound can only see evidence that the surgeon's work has not been done as well as it ought. The other school, which draws its limited experience from this present war, asserts that antiseptics are useless as such, and considers that they should not be used at all.

Sir Almroth Wright,[4] contending that the antiseptics in common use have no penetration and, therefore, cannot reach and destroy the organisms in the deeper portions of the wound, strongly advocated the use by continuous irrigation of hypertonic salt solution, which he had found to cause a marked inhibition of bacterial growth, and a rapid autodigestion and removal of sloughs.

Dakin, working with the hypochlorites, announced his results in the form of a new antiseptic for which he claimed that "wounds may be constantly irrigated for many days without producing noticeable irritation, and bacteriological examinations of the wound secretions demonstrate a vigorous antiseptic action. In addition to its antiseptic action the solution exhibits marked capacity for dissolving necrotic tissue." Many surgeons who tried it soon noticed that, though it did burn off sloughs in a short time, it was so irritating when used for continuous drip as to erode the skin where the fluid ran off the wound, and after a few hours the patients howled with the stinging, burning pain, and rebelled against it. It did clean the wounds, however, but their color was that of chemical irritation and not that of healthy granulating tissue. This was the experience of many workers, so that Dakin's solution gradually lost some of its vogue. Later Daufresne claimed to have succeeded in neutralizing the irritating element, and with this improved solution of Daufresne, Carrel has been able to secure a very rapid sterilization of wounds, which are then promptly sewed up.

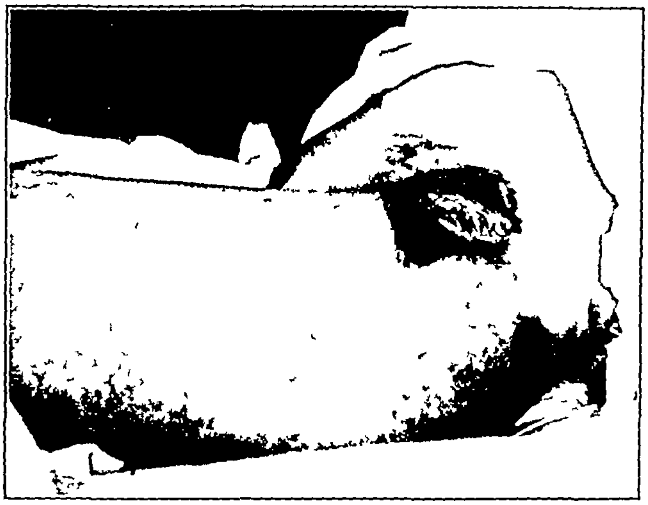

Fig 7.—Perforating shell wound of left iliac region, no fracture. Simple drainage and wet dressings. (Courtesy of the American Ambulance.)

Dakin subsequently proposed the use of chloramine as a valuable antiseptic. Others advocated hypochlorous acid. Gray, at Rouen, favors the complete excision and immediate suture of the wound. Some of the French surgeons are partisans of Carrel's method, others prefer silver nitrate solutions, still others strongly favor ether dressings, etc.

The results obtained by each worker depend in very large measure on the class of cases to which his particular method is applied. Carrel's hospital, for instance, is located at a short distance back of the lines, so that most of the patients admitted have been wounded only a short time before. The wounds are relatively fresh, and infection has not had time to develop to any great extent. The wounds are immediately enlarged and explored, every recess and cranny is laid open, and all foreign material (projectiles, clothing, etc.) removed. The wound is then filled with very fine catheters running into every corner, and through these little tubes is allowed to flow intermittently Daufresne's solution. There can be no doubt of the efficacy of this method, especially in wounds of the soft parts, such as constitute the majority of the cases received at this particular hospital.

---

[4] Wright, A. E.: Wound Infections and Their Treatment, Lancet, London, Oct. 30, Nov. 6 and 13, 1915.

Let us now go to a base hospital in or near Paris A large proportion of the wounded arrive from one to three weeks after their injury, having been cared for in the meantime by one or more surgeons in one or more hospitals They may have bad compound fractures, resected joints, penetrating or perforating wounds of the thorax, skull injuries, etc Infection has been going on a long time and, while the fundamental principles of treatment are the same, the conditions are not the same, and the treatment must be adapted to the conditions

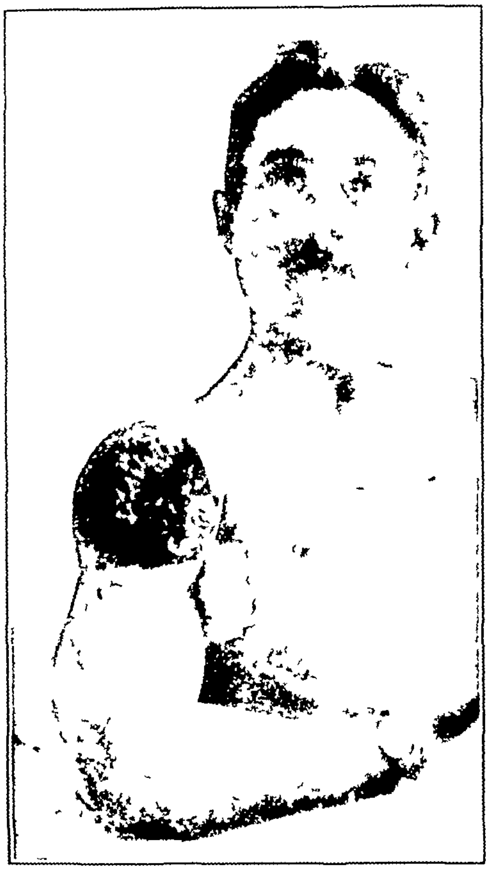

Fig 8—Shell wound of right shoulder, showing almost pure culture of B aerogenes capsulatus, but no clinical symptoms of gaseous emphysema Wound healed quickly under wet hypertonic saline dressings (Photograph by the author)

The excision of wounds advocated by Gray and others is applicable in only a few cases, in the majority of wounds it is out of the question, especially in old cases with long standing infection in which the elements of infection have become deeply lodged, in such cases attempts at excision and suture often lead to reinfection and breaking down of the wound

The point I wish to make is that no one method is applicable to all wounds The first indication is the thorough exploration of the wound, the painstaking removal of all foreign material, excision of sloughs, and ample provision for drainage At this stage continuous irrigation is of distinct value, because it dilutes the discharge and in this way greatly facilitates drainage The use of antiseptic solutions, such as Daufresne's, used according to Carrel's method, is to be advised if the wound is one that can be thoroughly made accessible to the action of the antiseptic, in which case it does not seem to make very much difference which of a number of antiseptic solutions is used At Ris-Orangis we divided the patients into series of ten, and treated the patients in each series with a different antiseptic solution, such as Dakin's, Wright's hypertonic saline, iodin solutions in different strengths, acetic acid solution, and sodium bicarbonate solution, with control cultures twice a week Our results failed to show any distinct difference in the power of the different antiseptics used to shorten infection and hasten granulation — when the wounds were properly drained the infection soon subsided — but they did show that continuous irrigation, while of distinct value during the active suppurating stage of the wound, should then be discontinued and dry dressings substituted Prolonged continuous irrigation seems to have a tendency to produce edematous, flabby granulations, and to retard the healing process

In badly comminuted fractures, which are nearly all complicated by infection, besides thorough drainage, all loose, detached pieces of bone should be removed, as they only lead to persistence of infection, but pieces of bone that are not detached should be left sacredly alone, because they often spell the difference between a useful limb and a flail one After two years in France, the only criticism of French surgery which I should dare to offer is that a few surgeons at the front have a tendency to make too many resections of comminuted fractures, thereby leading to pseudarthrosis and great shortening The proper treatment of fractures and of bone injuries in general is an important part of the work of the military surgeon Probably no one has done better work in that field than Dr Joseph A Blake, formerly of New York, who, by bringing together the ideas of a number of other surgeons with some of his own, has perfected an ingenious and simple method of treating fractures by suspension, with most creditable results Flint[5] of New Haven, working at Passy, near Sens, also used the suspension method with a modification of details in its application It is surprising how well most of these fractures unite under proper treatment, but when they do not unite,

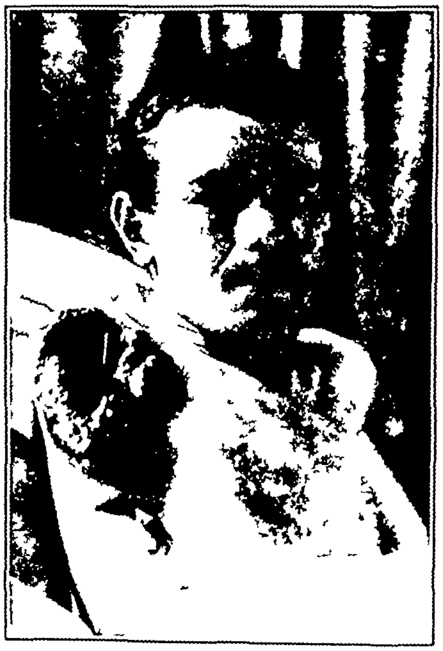

Fig 9—Right arm torn off by shell Wound badly infected Drainage and wet dressings (Photograph by the author)

contused and devitalized muscle, especially when the main blood vessels of the limb have also been involved in the injury This is followed by rapid systemic intoxication and septicemia

---

[5] Flint The Treatment of Fractures by Methods of Suspension and Extension Ann Surg June 1916

METHODS OF TREATMENT

In the surgery of civil life an injury is not usually exposed to so many evil influences, and the prompt attention it receives has much to do with the comparatively uneventful recovery of the patient If a soldier could keep relatively clean, and if, when wounded, he could be immediately taken to a well-equipped hospital and cared for, instead of having to be left lying for hours in dirt and mud with one or more wounds filled with dirty clothing, dead tissue, extravasated blood, and one or more foreign bodies, we might expect a better course and a more rapid recovery, and reconstructive surgical procedures could be employed sooner with shortening of disability

Much has been written about the treatment of wounds, especially in Europe, since the war has given such an importance to the subject The first great problem, since it is impossible to prevent the infection of these wounds, has been how to combat this infection It was early recognized that one important step in the right direction was an early and thorough exploration and cleansing of the wounds It was for this purpose that both the French and the English took advantage of the comparatively stationary position of their armies to establish immediately behind their lines field hospitals in which the wounds could receive the earliest possible attention This measure alone has been the means of saving thousands of men In the cases with abdominal wounds, for instance, it has been shown that the mortality depended absolutely on the time between the reception of the injury and the operation Unfortunately, the range of usefulness of these field hospitals has necessarily been somewhat restricted by the very conditions under which the work has to be done

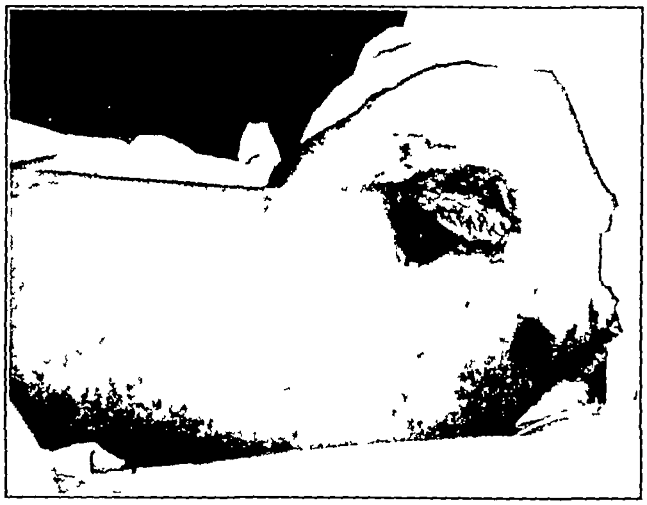

Fig 7 —Perforating shell wound of left iliac region no fracture Simple drainage and wet dressings (Courtesy of the American Ambulance)

And now we come to another great problem, and that is the use of antiseptics in an effort to bring about rapid sterilization and healing If I may again quote Sir Anthony Bowlby [1]

> It is at this stage that we find two different schools of thought amongst those who are not at the front as to what is best to be done in the treatment of the wound One school, which draws its experience mainly from the surgery of civil life, would persuade us that all our wounds, if properly treated, should be completely sterilized—at a single dressing if seen early enough—by the application of this or that antiseptic agent, and in any subsequently septic wound can only see evidence that the surgeon's work has not been done as well as it ought. The other school, which draws its limited experience from this present war, asserts that antiseptics are useless as such, and considers that they should not be used at all

Sir Almroth Wright,[4] contending that the antiseptics in common use have no penetration and, therefore, cannot reach and destroy the organisms in the deeper portions of the wound, strongly advocated the use by continuous irrigation of hypertonic salt solution, which he had found to cause a marked inhibition of bacterial growth, and a rapid autodigestion and removal of sloughs

Dakin, working with the hypochlorites, announced his results in the form of a new antiseptic for which he claimed that "wounds may be constantly irrigated for many days without producing noticeable irritation, and bacteriological examinations of the wound secretions demonstrate a vigorous antiseptic action In addition to its antiseptic action the solution exhibits marked capacity for dissolving necrotic tissue " Many surgeons who tried it soon noticed that, though it did burn off sloughs in a short time, it was so irritating when used for continuous drip as to erode the skin where the fluid ran off the wound, and after a few hours the patients howled with the stinging, burning pain, and rebelled against it It did clean the wounds, however, but their color was that of chemical irritation and not that of healthy granulating tissue This was the experience of many workers, so that Dakin's solution gradually lost some of its vogue Later Daufresne claimed to have succeeded in neutralizing the irritating element, and with this improved solution of Daufresne, Carrel has been able to secure a very rapid sterilization of wounds, which are then promptly sewed up

Dakin subsequently proposed the use of chloramine as a valuable antiseptic Others advocated hypochlorous acid Gray, at Rouen, favors the complete excision and immediate suture of the wound Some of the French surgeons are partisans of Carrel's method, others prefer silver nitrate solutions, still others strongly favor ether dressings, etc

The results obtained by each worker depend in very large measure on the class of cases to which his particular method is applied Carrel's hospital, for instance, is located at a short distance back of the lines, so that most of the patients admitted have been wounded only a short time before The wounds are relatively fresh, and infection has not had time to develop to any great extent The wounds are immediately enlarged and explored, every recess and cranny is laid open, and all foreign material (projectiles, clothing, etc) removed The wound is then filled with very fine catheters running into every corner, and through these little tubes is allowed to flow intermittently Daufresne's solution There can be no doubt of the efficacy of this method, especially in wounds of the soft parts, such as constitute the majority of the cases received at this particular hospital

[4] Wright, A E Wound Infections and Their Treatment, Lancet London Oct 30 Nov 6 and 13 1915

Let us now go to a base hospital in or near Paris A large proportion of the wounded arrive from one to three weeks after their injury, having been cared for in the meantime by one or more surgeons in one or more hospitals They may have bad compound fractures, resected joints, penetrating or perforating wounds of the thorax, skull injuries, etc Infection has been going on a long time and, while the fundamental principles of treatment are the same, the conditions are not the same, and the treatment must be adapted to the conditions

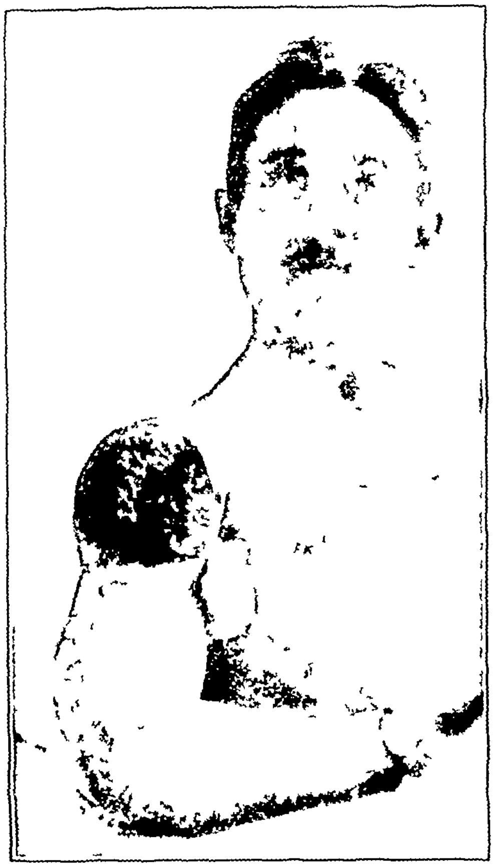

Fig 8—Shell wound of right shoulder showing almost pure culture of B aerogenes capsulatus, but no clinical symptoms of gaseous emphysema Wound healed quickly under wet hypertonic saline dressings (Photograph by the author)

The excision of wounds advocated by Gray and others is applicable in only a few cases, in the majority of wounds it is out of the question, especially in old cases with long standing infection in which the elements of infection have become deeply lodged, in such cases attempts at excision and suture often lead to reinfection and breaking down of the wound

The point I wish to make is that no one method is applicable to all wounds The first indication is the thorough exploration of the wound, the painstaking removal of all foreign material, excision of sloughs, and ample provision for drainage At this stage continuous irrigation is of distinct value, because it dilutes the discharge and in this way greatly facilitates drainage The use of antiseptic solutions, such as Daufresne's, used according to Carrel's method, is to be advised it the wound is one that can be thoroughly made accessible to the action of the antiseptic, in which case it does not seem to make very much difference which of a number of antiseptic solutions is used At Ris-Orangis we divided the patients into series of ten, and treated the patients in each series with a different antiseptic solution, such as Dakin's, Wright's hypertonic saline, iodin solutions in different strengths, acetic acid solution, and sodium bicarbonate solution, with control cultures twice a week Our results failed to show any distinct difference in the power of the different antiseptics used to shorten infection and hasten granulation — when the wounds were properly drained the infection soon subsided — but they did show that continuous irrigation, while of distinct value during the active suppurating stage of the wound, should then be discontinued and dry dressings substituted Prolonged continuous irrigation seems to have a tendency to produce edematous, flabby granulations, and to retard the healing process

In badly comminuted fractures, which are nearly all complicated by infection, besides thorough drainage, all loose, detached pieces of bone should be removed, as they only lead to persistence of infection, but pieces of bone that are not detached should be left sacredly alone, because they often spell the difference between a useful limb and a flail one After two years in France, the only criticism of French surgery which I should dare to offer is that a few surgeons at the front have a tendency to make too many resections of comminuted fractures, thereby leading to pseudarthrosis and great shortening The proper treatment of fractures and of bone injuries in general is an important part of the work of the military surgeon Probably no one has done better work in that field than Dr Joseph A Blake, formerly of New York, who, by bringing together the ideas of a number of other surgeons with some of his own, has perfected an ingenious and simple method of treating fractures by suspension, with most creditable results Flint[5] of New Haven, working at Passy, near Sens, also used the suspension method with a modification of details in its application It is surprising how well most of these fractures unite under proper treatment, but when they do not unite,

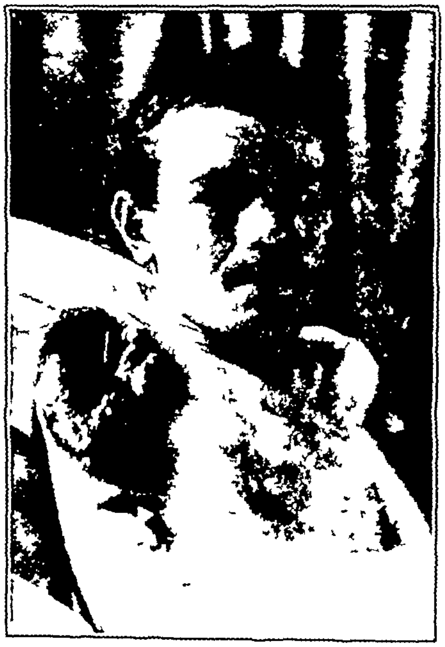

Fig 9—Right arm torn off by shell Wound badly infected Drainage and wet dressings (Photograph by the author)

because of a too great loss of substance, Albee's method of autogenous bone transplantation facilitates the restoration to usefulness of limbs which, in years past, would have been doomed to amputation Amputation is, as it should be, a measure of last resort, and, as the methods of dealing with infection and fractures are improving, the number of amputations is diminishing The importance of the after-treatment of these fractures and joint injuries was soon realized by the French surgeons, and the Service de Sante has established in different parts of France large hospitals, thoroughly equipped to give mechanotherapeutic, electrotherapeutic and orthopedic treatment to large numbers of men

---

[5] Flint The Treatment of Fractures by Methods of Suspension and Extension Ann Surg June 1916

The "plastic" restoration of losses of substance in the soft parts is another important phase of military surgery, and the keen surgeon, who is interested in plastic work, will find much stimulation in following the work of such men as Morestin of the Val de Grace, in Paris

The treatment of gas infection depends entirely on the stage of the disease when first seen If the injured part shows only a limited area of distention, with or without crepitation, the first indication is to lay open the infected area by multiple free incisions, and to remove all foreign material, the incisions are to allow the escape of gas, and in this way to prevent the destruction of muscle tissue After ample drainage has been provided for, continuous irrigation may be tried Taylor, after extensive experiments, advises the use of a 1 per cent solution of quinin hydrochlorid If, in spite of these measures, the crepitation continues to extend, no time should be lost in vain hope, the limb should come off at once If the infection is located in the thigh, the amputation should be at or near the hip joint Various methods have been tried, such as subfascial injections of oxygen gas or peroxid, but the results have not given much faith in such measures, in spite of their apparently sound theoretical basis

The greatest lesson to be learned from the surgery of this war can be summed up in the two words, "intelligent conservatism"

THE PRODUCTION OF AN ANTIPOLIOMYELITIC SERUM[*]

JOHN W NUZUM MD
Resident Pathologist Cook County Hospital
CHICAGO

The many deplorable deformities attendant on infantile paralysis, together with the high mortality of recent epidemics, demands that a most intensive study be made to discover some therapeutic measure which may curtail the ravages of this disease A study of the recent epidemics in Chicago, New York and elsewhere has revealed certain constant bacteriologic findings What appears to be the same peculiar micro-organism has been repeatedly isolated from the tonsils,[1] brain, spinal cords[2] and cerebrospinal fluids[3] of patients in widely separated cities The presence of this polymorphous organism so constantly in the spinal fluid during life,[4] even shortly after the onset of the paralysis, and the discovery that the coccus remains in the spinal fluid and can be readily isolated in pure culture several weeks after the onset of the disease, not alone offers a most important clinical diagnostic procedure but also suggests at once a source for obtaining the organisms both for experimental biologic studies and for animal immunization experiments There is evidence to show that the coccus so constantly present in poliomyelitic spinal fluids is not present in normal cerebrospinal fluids, nor has it as yet been isolated from the spinal fluid of patients with scarlet fever, varicella, diphtheria or other diseases presenting more or less confusing clinical similarity with infantile paralysis These studies will be made the subject of a subsequent communication

A therapeutic measure which may ultimately offer hope in this disease would seem to be the production of a specific antiserum for the causative organism The vital question apparently centers on whether or not the quantities of antibodies produced in animals by methods of immunization will suffice to exert either sufficient antibactericidal action or, what may be of even greater moment, to effect the neutralization of the toxins formed by the bacteria It must be admitted that the most efficient antiserums have been obtained with those organisms which produce potent toxins The meager evidence at hand suggests that the pathologic changes in poliomyelitis may be the result chiefly of the endotoxic products of the micro-organism If this proves to be correct, then the problem appears more complex since endotoxins do not as a rule produce highly potent antiserums possessing great therapeutic value in the treatment of human infections

To determine these questions animal immunization experiments were begun, Nov 1, 1916 A detailed study of the production of an immune serum for the organism isolated from poliomyelitic cases forms the basis of this paper

IMMUNIZATION OF ANIMALS

Three healthy sheep, two lambs and four rabbits were selected and immunized according to the rapid method described by Amoss and Wollstein[5] They showed that an equally potent serum can be produced in from eight to twelve weeks by their method, instead of in from eight to twelve months, as required by previous immunization methods The animals received intravenous injections of living organisms in increasing doses on three successive days, followed by periods of rest of seven days The twenty-four hour growth on a dextrose agar slant was suspended in 2 c c of sterile normal salt solution, and 0 1 c c of this suspension, or one twentieth of an agar slant, was slowly injected in 10 c c of physiologic sodium chlorid solution into the jugular vein of each sheep The rectal temperature was recorded hourly, and a febrile reaction following each single injection served roughly to gage the optimum dosage Twenty-four hours after the first injection, 0 2 c c suspension and on the third day 0 3 c c of the foregoing suspension of bacteria in 10 c c saline solution were injected intravenously This was followed by a period of rest of seven days when the second series of injections was instituted

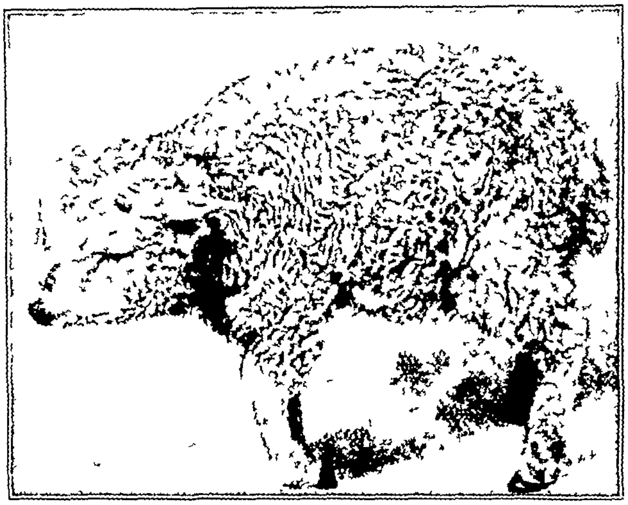
[5] Amoss H L and Wollstein Martha A Method for the Rapid Preparation of Antimeningitis Serum Jour Exper Med 1916 23, 403

0 3 c c being given the first day, 0 4 c c the second day and 0 5 c c, or one fourth of an agar slant, the third day The first series of injections consisted of a group of five representative strains of the coccus isolated from poliomyelitic cerebrospinal fluids For the second series, five strains isolated from poliomyelitic brains and cords at necropsy were utilized To each of these representative groups new strains have been added, until now at the fifth series of injections each group consists of ten different strains of the micrococcus

Small desensitizing doses are regularly employed during the first injection of each series, and after a lapse of two hours the full dose is given, the danger thus being avoided of any anaphylactic reaction and sudden death of the animals Autolysates of the coccus were prepared by suspending cultures in physiologic sodium chlorid solution and incubating for twenty-four hours These autolysates were alternated with the living organisms in the serial injections The maximum dosage given to date consisted of 4 c c or two agar slants from the pooled growth of twenty different strains of the organism Those strains of the coccus which are not agglutinated in varying dilutions of the immune serum have been incorporated in the groups used for serial immunization, thus producing a polyvalent potent antiserum



Flaccid paralysis of the left foreleg of a young lamb undergoing immunization complete recovery twelve hours after intraspinal injection of 1 c c immune serum

The progress of antibody formation in the sheep serums was studied by agglutination, complement fixation and more recently by animal protective experiments A steady rise in the antibody content of the serums has been noted following each serial injection Seven days after the fourth serial injections, agglutination was complete at 1 5,000 dilution of the serum, and complement fixation was complete at 1 200 Thus far, as might be expected, it has been quite definitely proved that the organism of poliomyelitis stimulates the formation of antibodies in the blood stream of animals undergoing the process of immunization

VIRULENCE OF THE MICRO-ORGANISM OF POLIOMYELITIS

In studying the virulence of the organism, young rabbits from four to eight weeks of age and of approximately equal weight and size were selected in groups of threes and inoculated intravenously with decreasing doses of various strains of the coccus obtained both from brains and human poliomyelitic spinal fluids Later it was found more satisfactory to inoculate white mice intraperitoneally in series These animals are quite susceptible to the germ, and rapidly develop a fatal septicemia One-tenth c c of Strain Leitz caused the death of white mice in fourteen hours The amount of cultures required to produce paralysis or death in rabbits is relatively large Recent isolated cultures of the coccus are naturally more virulent than strains incubated for varying periods of time It should be admitted that certain strains exhibit but slight pathogenicity, even when recently isolated

ANIMAL PROTECTIVE EXPERIMENTS

Table 1 indicates that the polyvalent immune serum possesses a certain limited degree of protective value for white mice Two-tenths c c of the serum protected against ten minimum lethal doses of Strain Leitz Normal serum, however, and even sterile bouillon in 1 c c amounts exhibits some definite degree of protective value The conditions of this experiment are perhaps rather severe since ten minimum lethal doses of Strain Leitz were employed—a strain recently isolated in a fatal human case and not as yet incorporated in the lots employed for the immunization of the animals

Table 2 indicates the protective value of immune serum as compared with normal serum and bouillon when young rabbits are utilized The strain Anna employed in this experiment was recently isolated from human poliomyelitic spinal fluid One-tenth c c of the immune serum protected a 343 gm rabbit against one minimal lethal dose of Strain Anna It is evident from this table that normal serum and even bouillon were able to delay the course of the infection in rabbits, but apparently could not protect against either paralysis or an ultimate fatal termination of the infection

After it had been determined that immune serum possessed certain properties not present in normal serums a study was undertaken to determine the mechanism of the protective action White mice were injected intraperitoneally with varying dilutions of immune serum and constant quantities of the organisms At the end of thirty minutes and again at the expiration of one hour, a few drops of the peritoneal exudate were aspirated from the peritoneal cavity, and stained specimens were examined microscopically It was determined that immune serum in vivo causes a rapid exudation of cells into the peritoneal cavity, chiefly polymorphonuclear leukocytes and smaller numbers of mononuclear lymphocytes At the end of an hour most of the bacteria are readily visible within the leukocytes The few remaining extracellular organisms appear clumped together, and many are markedly swollen to several times their normal size Others have apparently undergone complete disintegration Pfeiffer's phenomenon was complete, or nearly so, at the expiration of one hour with the higher concentrations of the immune serum

In an attempt to determine whether or not the coccus of poliomyelitis produces toxins, eight day broth cultures were passed through a Berkefeld filter, and varying amounts of the filtrate were injected into the peritoneal cavity of mice Relatively large amounts of the filtrate were required to produce toxic effects or death

PROTECTIVE EXPERIMENTS IN MONKEYS

For my next experiments I utilized monkeys, since it is generally admitted that poliomyelitis can be experimentally produced in these animals Furthermore, the histopathologic changes in the monkey closely simulate the disease as we are familiar with it in man Accordingly, three healthy monkeys were selected, and after the lethal dose of the organism for the monkey had previously been determined, the first animal was inoculated intraspinally with 1 c c of Strain Leitz The second animal received a similar dosage of the same culture plus 1 c c of normal sheep serum The third monkey received an intraspinal injection of 1 c c of Strain Leitz plus 1 c c of polyvalent immune serum The results follow

TABLE 1—ANTI-INFECTIOUS POWER OF POLYVALENT SERUM *

Strain Leitz	1 C c Pooled Normal Sheep Serum	1 C c Sterile Bouillon	0 1 C c Immune Serum	0 2 C c Immune Serum	0 3 C c Immune Serum	0 4 C c Immune Serum
10 minimum lethal doses	Protection in 2	Protection in 1	Protection in 3	Protection in 4	Protection in 4	Protection in 4

* Illustrating the protective value of immune serum when white mice are inoculated simultaneously with serum and cultures 0 2 c c of the polyvalent antiserum protected against 10 minimum lethal doses of Strain Leitz

Experiment 1 (Case 10) —Dec 8, 1916, at noon, a large *Macacus rhesus* monkey was etherized, and the lower lumbar region shaved and sterilized Lumbar puncture was performed, and 1 c c of clear spinal fluid withdrawn Intraspinal injection was given of 1 c c of a mixed brain and spinal fluid culture of Strain Leitz plus 1 c c of normal sheep serum At 4 p m the animal had recovered from the anesthetic and was quiet in the cage December 8, at 9 p m, the animal was sick, and not attentive to surroundings December 9, at 10 a m, the monkey was acutely ill It lay prostate in the cage, could not sit up, and fell over when lifted upright There was marked weakness of the right front arm with definite wrist drop Lumbar puncture was performed, and 1 c c of clear spinal fluid withdrawn Stained smear of the sedimented spinal fluid revealed many polymorphonuclear leukocytes Many gram-positive diplococci were scattered uniformly throughout the field, chiefly extracellular Cell count revealed 920 per cubic millimeter

One c c of immune serum was injected very slowly intraspinally December 10, at 10 a m, the animal exhibited a complete flaccid paralysis of both arms and a marked weakness of the hind legs Lumbar puncture was performed, and only a few drops of clear spinal fluid obtained Stained smears revealed marked agglutination of the organisms with swelling and dissolution of many of the bacterial bodies and vacuolization of the leukocytes There were many intracellular organisms One platinum loopful of the spinal fluid was inoculated into each of a series of agar tubes, and blood agar plates were made A similar procedure was carried out with the spinal fluid before the administration of immune serum At the end of twenty-four hours' incubation, the average number of colonies per plate before injection of the immune serum was eighty-four Twenty-four hours after the intraspinal injection of the immune serum, only twenty-four colonies were counted per plate This was interpreted as a definite antibactericidal action of the immune serum in vivo

December 10, the monkey died in a convulsion, despite having received another injection of the antiserum

Necropsy—There was marked hyperemia of the pia-arachnoid vessels over the cerebral cortex of the brain The brain tissue was edematous There was no visible exudate anywhere over the brain or spinal cord The gray matter of the cord was hyperemic There were no visible hemorrhages in the leptomeninges

Microscopically, there was marked interstitial infiltration of lymphocytes in sections of both brain and cord There was hyperemia of the capillaries in cross section There was definite degeneration of the motor ganglion cells Neurophagocytosis was visible in the cord and also in the intervertebral ganglia

On bacteriologic examination, a pure culture of the original gram-positive coccus was obtained in cultures from the cord, brain, spinal fluid and heart's blood

An analysis of this case shows, first, that normal sheep serum afforded little if any protection against the infection Twenty-four hours after the inoculation, and at a time when the course of the infection was undoubtedly decided, immune serum exhibited certain limited bacteriolytic properties, but could not save the animal's life

Experiment 2 (Case 12) —Dec 8, 1916, at 10 a m, a large *Macacus rhesus* monkey was etherized, and 1 c c of Strain Leitz slowly injected intraspinally after the previous withdrawal of 0 5 c c of clear spinal fluid December 9, at 9 a m, the animal lay prostrate in the cage, and was very weak and tremulous He was unable to support himself in an upright position Lumbar puncture was done, and a very few drops of clear fluid obtained Stained smears revealed many small diplococci, sharply staining, and evenly distributed throughout the field Bacteria were chiefly extracellular There were many polymorphonuclear leukocytes and smaller numbers of lymphocytes One c c of immune serum was injected intraspinally At 10 p m the animal was resting quietly He refused food Rectal temperature was 38 C (100 4 F)

December 10, the monkey was active and bright in his cage Lumbar puncture was done, and smears revealed only a very few swollen diplococci, chiefly intracellular Cell count revealed 382 cells per cubic centimeter December 18, the animal remained well No paralysis was present

In this case we feel that the immune serum was able to prevent a fatal course of the disease, and apparently arrested the infection a considerable period of time after the inoculation of the bacteria

TABLE 2—PROTECTIVE VALUE OF IMMUNE SERUM IN YOUNG RABBITS *

Weight of Rabbit, Gm	Amount of Culture, C c	Protective Substance	Result
314	0 2	None	All dead within 48 hours
815	0 4

356	0 6	0 3 c c.	
		Normal Serum	
270	0 2	0 2 c c	Died after 9 days
275	0 4	0 4 c c	Died after 4 days
286	0 6	0 6 c c	Died after 3 days
		Bouillon	
318	0 2	0 2 c c	Survived
320	0 4	0 4 c c.	Flaccid paralysis Death in 6 days
330	0 6	0 6 c c	Died after 5 days

* Illustrating the protective value of immune serum as compared with normal sheep serum and sterile bouillon Simultaneous intravenous injection of serum and cultures after previous incubation for thirty minutes

Experiment 3 (Case 14) —Dec 8, 1916, at 2 p m, a small ring-tailed monkey was inoculated intraspinally with 1 c c of Strain Leitz plus 1 c c of immune serum after the previous withdrawal of clear spinal fluid Serum and organisms were incubated together for thirty minutes previous to inoculation into the monkey

December 9, at 10 a m, the animal raced and climbed about the cage apparently little worse for the infection December 18, the monkey remained well

In this experiment the conditions were not entirely analogous to those of the former cases because of the incubation of the serum and culture previous to inoculation The animal utilized was also of a different species From the foregoing series of experiments, however, it would seem fair to conclude that immune serum possesses the power to protect monkeys against an otherwise fatal result

During the course of immunization of the sheep, one of the lambs which had received but two series of injections — one intraperitoneally and the second intravenously — developed a complete flaccid paralysis of one front leg The limb was carefully examined to exclude any possible trauma A marked flaccid paralysis was present, and the animal limped along on the other three legs, dragging along the paralyzed extremity in a flail-like manner At no time during a careful observation of ten hours did the animal bear any weight on the paralyzed limb Ten hours after the onset lumbar puncture was performed, and 1 c c of clear spinal fluid was withdrawn A twenty-four hour culture yielded a growth of the gram-positive coccus of poliomyelitis One c c of immune serum was injected intraspinally The following morning the animal had regained complete use of the paralyzed leg and has remained well since

The final test of the value of any antiserum is its therapeutic efficiency in human infections I do not wish to apply, at this time, the results of animal experiments to man Suffice it to say that we have under treatment at the present time a child afflicted with the cerebral type of poliomyelitis The gram-positive coccus has been isolated on several occasions from the spinal fluid by the physician in charge of the case This patient has received several intraspinal injections of immune serum after the serum had been passed through a Berkefeld filter and tested for sterility by repeated cultural experiments Thus far it has been possible to sterilize the cerebrospinal fluid and to bring about a certain definite improvement in the clinical symptoms of the patient The details of this case will form the subject of a separate communication From the evidence at hand it would seem that poliomyelitis is in many cases — probably always in the acute fulminating types of the disease — at first a general bacteremia with the rapid localization of the microorganisms to the central nervous system If this ultimately proves to be true, it would seem fair to conclude that immune serum may be of great value in the treatment of this disease

SUMMARY

1 By the process of animal immunization with the organisms regularly isolated from the spinal fluids and the central nervous system of human poliomyelitic patients, an antiserum can be produced Its therapeutic limitations are as yet unknown

2 Antiserum prepared in this manner contains agglutinins, opsonins and complement fixation bodies, as well as exhibiting certain antibactericidal properties

3 It would seem fair to conclude that with potent polyvalent antiserum prepared in this manner, some definite therapeutic value might be anticipated in human cases of the disease

GENERAL HEALTH CONDITIONS IN BELGIUM

AFTER TWO YEARS OF RELIEF WORK BY THE COMMISSION FOR RELIEF IN BELGIUM

WILLIAM PALMER LUCAS, M D
Physician in Chief of the Children s Department, University of California Medical School
SAN FRANCISCO

At the request of the Commission for Relief in Belgium, I spent May, June and July in that part of Belgium occupied by the Germans, in the examination of present health conditions of the population, with special regard to the welfare of the children In this investigation I had the unremitting aid and counsel of the Belgian physicians and surgeons The liberty of movement which I enjoyed, as a member of the American commission, enabled me to perform a broad survey of conditions, which, under present military restrictions, is not possible for the very able Belgian specialists themselves to undertake It is difficult to generalize on the health of the whole population of the country even in normal times, when the aid of every branch of mortality and morbidity statistics can be brought to bear on the investigation, and therefore any generalization which I make in regard to Belgium, in the condition of stagnation in civic functions which exists today, is even more difficult I had access to many local statistics, hospital reports and individual private statements and information which rendered it possible to reach some conclusions which I believe are not only of value to the relief work, but also of interest to friends of the population

Broadly viewed, the objective of the inquiry was to determine what the health and nutrition of the population were as a result of the relief which has been given, what changes might be desirable in the character and manner of feeding, and if any other measures for the general health could be instituted

In a general way, conditions of health in normal times vary greatly in all countries between different economic and social classes The present economic and political situation in Belgium sharply accentuates these class differences, and therefore points to a discussion of the situation class by class From this point of view we may divide the population into the well-to-do or so-called upper classes, agricultural classes, and industrial or lower commercial classes

Well-To-Do Classes—These classes in Belgium, as in any other country, are the last to suffer in any food emergency, and may therefore be dismissed at once as being today in as good physical condition as they were before the war Certainly there is no particular increase of illness among these classes, and as there are always native provisions to be bought at a certain price in every famine, they do not suffer from malnutrition The enforced economy and temperance of even these classes has probably had beneficial results from a health point of view Furthermore, the almost universal response to the duty imposed on this class to care for the less fortunate has given stimulation and occupation, which has possibly had beneficial results and has, at least to some extent, neutralized any damage which might occur from overanxiety

The Agricultural Classes—The agricultural communities throughout Belgium may also be said to be in a very good physical state, indeed, so far as one can judge, their material condition has improved steadily since the arrival of the 1915 harvest Having first access to the produce of the land, it is obvious that they do not deprive themselves or their families of nourishment, and the high prices which they receive for their surplus produce have increased their resources, so that they will undoubtedly be in a better condition after the war than they were before

These two classes probably embrace about 35 per cent of the entire population of the occupied territory of Belgium

Industrial and Minor Commercial Classes—When one turns to the industrial communities in the large cities, which have a greater percentage of the population dependent on the paralyzed industries and commerce of the country for their livelihood, there exists a situation in which the general health is open to more doubt and where, in any event, it is maintained only by extensive organization of relief and protective measures In a general way, an average of 9,000,000 pounds of fat and 160,000,000 pounds of cereals are monthly imported from abroad by the relief commission and delivered mainly to these classes, and with this supply, together with such supplementary native supplies as can be procured, their nutrition must proceed As this class must embrace about 5,000,000 people, it is obvious that their food supply is very close to the actual necessities of nutrition It is chiefly with regard to the efficiency of this supply, therefore, and the results on the nutrition of the population for nearly two years that this inquiry has been directed

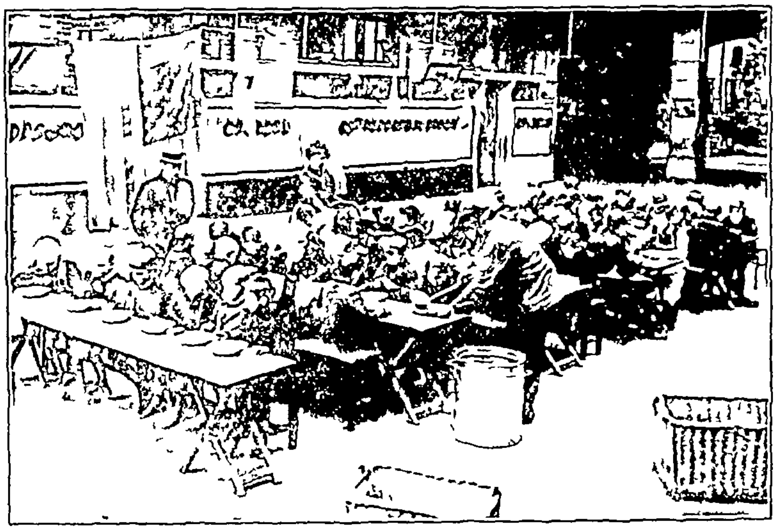

Fig 1—Type of school lunch which the Commission for Relief in Belgium is instituting throughout the country as a result of the recommendations in this report

It must be stated at once that, even with these supplies, the population has existed on the narrowest margin of dietary necessaries, and that the very careful balancing of the protein, fat and carbohydrate values of this minimum ration must, as in the past, continue to be a matter of concern The constantly changing situation as to local meat and milk supplies, by seasonal changes and gradual depletion of stock, must be watched and met, for while the general condition of this class, with the exception of the increase in tuberculosis, is not acute, certain definite situations are developing which must be reinforced or serious results will ensue It may be said at once that the increase in tuberculosis appears to me to be mainly a factor of nutrition, and if conditions were now to return to normal, the unaffected adults would, on liberal nourishment, probably return to their former health conditions within two or three months This, of course, is not true of those who have become affected with tuberculosis, nor is it so true of the adolescent children especially, who are probably suffering more than any other single group in this class, although the radical measures now adopted of separate and extra feeding for the adolescent children in the schools may stem this deterioration I am happy to say that the great devotion and stimulation of relief work for the infants and children of Belgium has raised their condition on the whole to rather better than normal Before a summary of the specific conditions of each of the age divisions of this class is given, it is desirable to discuss the tuberculosis situation as this bears on the entire population

TUBERCULOSIS SITUATION

That the undernutrition of this class especially is mainly responsible for the fact that tuberculosis is increasing rapidly will be easily realized when one considers that the average consumption of fat lies somewhere between 20 and 30 gm per day per individual This, of course, is far too low, and especially so for the adolescent years The lack in meat, both from the question of supply and on account of the high prices, makes it almost impossible for this class to obtain any animal protein in this way The growing lack in the milk supply is another important factor in this nutritional problem and during the coming winter, when there is a diminution in the native supply of vegetables and fruit, which, to a certain extent, this class is able to procure in summer, the ration will be considerably lower than it was during that season, and unless something can be introduced especially for the tuberculous of this class the whole tuberculosis situation will undoubtedly progress more rapidly than it has in the past As I shall show from the hospital reports and statistics many cases of tuberculosis which were supposed to be cured are reappearing From the fact that the sanatoriums and hospitals are all crowded, a continually increasing number of foci for the distribution of tuberculosis are rapidly forming and, under the present military conditions, it is difficult to carry on any educational campaign or any of the ordinary preventive sanitary measures against such a widespread increase in this disease

The staff of every hospital and dispensary which I visited commented on the marked increase in the number of patients who are attending their clinics The increase in the tuberculosis clinics was perhaps most marked of all, being in some cases over 100 per cent more than they were before the war Every tuberculosis sanatorium in Belgium is crowded, and the waiting lists of all the sanatoriums are larger and the cases waiting more acute than they were before the war The following statements from various hospitals indicate the same conditions

Dr Verhoogen, the chief of the medical service of St Jean Hospital Brussels, states that there has been a considerable increase in the number of patients with tuberculosis coming to his general medical clinic He finds that persons with old arrested cases of tuberculosis are returning in large numbers — cases which he had considered cured for a period of more than five years — and that their relapses are of a rapid and grave character He finds that there is a more acute involvement of the lungs, there are many more cases of glandular tuberculosis and tuberculosis of the peritoneum than formerly, and he is especially struck by the increase in cases of tuberculous meningitis, probably the most fatal and fulminating type of tuberculosis that exists He states the significant fact that his wards, which normally have ninety-eight beds, have had to be enlarged to 106, and that whereas during the summer he usually has had very few patients, in June and July, 1916, he had all his beds filled, and 35 per cent of the cases were active tuberculosis, a higher percentage of tuberculosis than he has seen before in his wards

In the St Pierre Hospital in Brussels, Dr Naewelaers, chief of the children's service, states that for the year 1912 he had only fifty-three patients with active tuberculosis in his infant ward, and in 1915 he had 125, but that in the first five months of 1916 he has had fifty-five, which, for the year 1916, would make 133 cases, and they have been more severe than formerly The surgeons in all the childrens hospitals state that persons with operative cases are much slower in recovering, and that open wounds in many cases refuse to close

Fig 2 —Canteen for debilitated children showing Dr and Mme Lathoir This is the largest canteen for debilitated children in Belgium Last summer 1 500 children were being fed daily

The chief surgeon of the throat clinic of St Pierre Hospital in Brussels states that the increase of tuberculous conditions of the throat, which is one of the rarer forms of tuberculosis, has been most marked He gives the following figures for his clinic In 1912, 1 5 per cent of his patients had tuberculosis of the throat, in 1913, 1 per cent , in 1914, 1 5 per cent , in 1915, 2 2 per cent , and for the first five months in 1916, 4 per cent , making an increase of 150 per cent between 1914 and 1916

The chief surgeon of the children's clinic of one of the largest hospitals in Brussels reports the following figures of increase in tuberculosis During the years 1909 to 1913 there was an average of 3 34 per cent of his patients who had tuberculosis , in 1914, 5 9 per cent had tuberculosis, in 1915, 5 4 per cent , and the percentage for the first five months of 1916 was 12 2 per cent

Dr Tieren, president of the Antwerp Provincial section of the Belgian League Against Tuberculosis, states that since 1913 the number of new patients with tuberculosis who came to the Institute Van den Nest increased two and one third times during the first four months of 1916, as compared with the same months of 1915 He states that not only have the cases of tuberculosis become more frequent, but that they are also more malignant , cures are much harder to obtain, and old cases, apparently cured for five years or longer, are reappearing in large numbers

Dr Wysen, head of the hygienic service of Antwerp, gives the following figures to show the number of deaths from tuberculosis (the percentages are expressed on the total number of deaths in Antwerp, not counting deaths in the floating population) For the first seventeen weeks of each year the mortality from tuberculosis has been as follows 1909, 8 per cent , 1910, 8 3 per cent , 1911, 8 6 per cent , 1912, 8 6 per cent 1913, 7 1 per cent , 1914, 9 per cent , 1915, 9 5 per cent , and 1916, 13 2 per cent

In Namur also the mortality from tuberculosis has increased, the number of deaths from pulmonary tuberculosis and tuberculous meningitis for the year 1915 was thirty-eight, while for the first half of 1916 it had already reached thirty-four In the Agglomeration of Brussels the following figures show the increase in mortality from pulmonary tuberculosis In 1913 there were 502 deaths from pulmonary tuberculosis in the Agglomeration of Brussels during the first semester , for the same period in 1914 there were 521, for 1915, 506, and for the first semester of 1916, 662

Dr Lorent, physician for the poor in one of the large poor sections of Brussels, states that since the beginning of the war and more especially since the beginning of the year 1916, cases of tuberculosis have become more frequent and have taken a more rapid and serious course The physicians from one of the large dispensaries in Antwerp state that the greater part of the adults who visit the dispensary for the first time declare that their weights have diminished, and they state, the average diminution to be over 5 kg , or about 10 to 11 pounds Among tuberculous patients whom they are treating and to whom they have been giving a supplementary diet, they note that out of ninety-five tuberculous patients receiving the supplementary meals, fourteen gained from 0 5 to 3 kg , twenty-three kept their previous weight, and fifty-eight lost from 1 to 9 kg during an observation period of one month During the same period, of eighteen nontuberculous patients who were under observation but who did not receive a supplementary diet, none increased in weight, five remained stationary and thirteen lost from 1 to 7 kg , that is, from 2½ to 15 or 16 pounds The same dispensary gives the following figures for the attendance at their clinic For the first three months of 1915 they had an average of 158 visits a month, and for the first three months of 1916 an average of 589 visits a month The actual cases of tuberculosis had more than doubled during this period

Dr Gengou, secretary of the Antituberculosis Society of Belgium, states in a report which he has drawn up, based on a questionnaire sent to all the antituberculosis societies in Belgium, that the information obtained is unanimously to the effect that the spread of tuberculosis has progressed among the poorer classes, and that among the children of these classes the surgical types of tuberculosis have increased very markedly, for instance, from Verviers, Dr Gustin states that there is a particular increase in tuberculosis among the working classes in that region He is of the opinion that this increase is due both to the present conditions which have been created throughout the country and to the fact that the sanatoriums for tuberculosis are all filled, so that acute cases not isolated are spreading the disease rapidly At Liege, Dr Malvoz points out that the increase in mortality from tuberculosis there shows a change for the years 1913, 1914 and 1915 of from 164 to 170 to 179, and for the first trimester of the years 1915-1916, from 53 to 64

Among children, Dr Gengou finds from his questionnaire that the unanimous opinion of physicians throughout Belgium is that tuberculous adenitis has increased from five to tenfold Some go much further in their figures, as, for example, Dr Mine of Lockern, who states that none of the children of the working and middle classes in his community have escaped glandular congestion This does not necessarily mean tuberculosis in an active form, but certainly indicates a lower resistance and a field ready for tuberculous infection

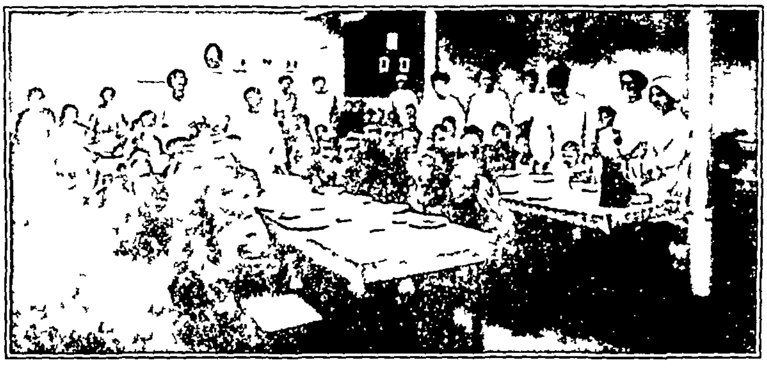

Fig 3—Canteen for debilitated children located in a cellar in Brussels

Dr de Moor, chief physician of the public schools in Brussels, gives the following figures for one of the public schools in Brussels

Out of 485 boys between 6 and 14 years of age, 305, or 63 per cent, have developed cervical glands, and 190 of this number, or 40 per cent of the total number, have developed considerably larger glands, 1 65 per cent having glands which suppurate In another large school, 482 children out of 683, or 70 per cent, have developed cervical glands, and 276 of these, or 40 per cent, have quite large glands, while 1 per cent have glands which suppurated

These conditions are especially true of the large centers, such as Brussels, Antwerp, Ghent, Liege, Mons and Charleroi It is to meet this situation in the schools that it has been proposed, in a report which I made to the relief commission, to extend school lunches This is especially important for adolescent children in the upper form schools The school population of Belgium for the lower form schools is approximately 885,000 children, and during the last semester they have been given a supplementary school lunch provided by the commission It was determined, if it should be possible to get the necessary imports, to extend these school lunches to the upper form children from the beginning of the next semester, October 1 This would probably include about 1,500,000 children in Belgium, or approximately the total needy schoolchildren population, and from 500,000 to 750,000 children in the North of France It is especially important for the better development of the children and for the protection of the pretuberculous and tuberculous individuals who must remain at home that there should be an increased diet, with special measures to overcome the present deficiencies in fat

As I have already stated, the tuberculosis sanatoriums and hospitals are all filled and have large waiting lists Many of the sanatoriums for tuberculosis are now finding it difficult to obtain a sufficient supply of milk for their patients The reduction amounts to as much as 50 per cent in some cases With the increased necessity for giving these patients supplementary diet, together with the patients who must remain at home and should also have additional supplies of milk and fat, the problem of special imports for the sick, especially the tuberculous, is a very important one

The tuberculosis situation demands increased activity, but under present conditions it is very difficult to carry on an active antituberculosis campaign There should be, however, an increased facility for the supplementary feeding of tuberculous patients New dispensaries should be opened in the large centers where they do not exist at present, and from these centers, with special visiting nurses, a considerable amount of preventive work can be carried on It is especially important to reach homes in which there are patients with active cases of tuberculosis who at present cannot enter tuberculosis sanatoriums Special supplementary diets should be furnished these homes, and where possible provision should be made for sending children from them to the country or to temporarily improvised sanatoriums

In connection with the deficiency in fat and animal protein, the lack of one of the most important food supplies should be noted Already throughout Belgium the milk supply is not sufficient for the needs of the children and the sick, and this is especially true of the larger cities Milk, as at present sold, is not only very expensive, but it is also of poor quality, being diluted or skimmed The commission is already taking active measures to obtain special herds of cows to supply a certain amount of fresh milk to children's canteens or hospitals, but the natural supply can nowhere meet the demand, and during the coming winter the present supply will be even smaller than it is, hence definite and active measures should be taken for supplying some good milk products, such as condensed milk or milk powder, for the children and sick of Belgium

GENERAL ADULT POPULATION

That the condition of the adults of these classes is being somewhat disturbed, although not severely damaged, is evidenced by such facts as these It is the current opinion of employers and those competent to judge that the laboring man of the working classes in the cities and industrial centers is not able to do the amount of work he was formerly capable of doing His energy and power of production are considerably less, and he becomes fatigued much more easily than usual Reports from physicians who care for these classes note that there has been marked loss of weight, even among those who are not sick, since 1914, they estimate that about 80 per cent of the population have lost weight and that the average loss is from 2 to 3 kg, that is, from 4½ to 7 pounds This they attribute to insufficient nutrition, especially to the low quantity of fat and animal proteins which they are receiving, to mental worry and to the epidemic of grip which was very extensive during last winter and spring

Likewise, among schoolchildren, one of the reports from a large public school for boys shows that out of 773 boys, for the year 1914-1915, 75 per cent increased in weight, 15 per cent diminished, and 10 per cent remained stationary In the same school during the year 1915-1916, out of 607 boys, 68 per cent gained weight, 25 per cent diminished, and 7 per cent remained stationary

DIMINUTION IN MATERNAL NURSING

Another keen index of the subnormal condition of the adults of these special classes may be found in the records of the maternity hospitals frequented by the wives of working men The reports from maternity hospitals at Antwerp, Brussels and Liege all show that the weights of the babies born at the present time are less than the average of infants before the war For instance, Dr Dauve of Antwerp, chief of the maternity hospital of Ste Anne, states that the new-born are generally debilitated and have the appearance of prematurely born infants whose weight and length are under average, they weigh on an average from 2,000 to 2,500 gm and measure 47 cm (19 inches) (The average weight of a new-born infant should be between 3,000 and 3,500 gm and the average length 20 inches) The lactation of the mothers leaves much to be desired, and the gain of the new-born, which should be 180 gm a week on an average, is now only 50 gm In several maternity hospitals, the incubator rooms, containing from four to twelve incubators, were always found filled, and the statement was made by the chiefs of the services that before the war there were rarely more than one or two underweight or premature infants in these incubators at any one time, and often there would be none for several months, whereas, during the past year these incubators have never been empty At the St Pierre Hospital, Brussels, many of the underweight infants have to be kept in improvised incubators

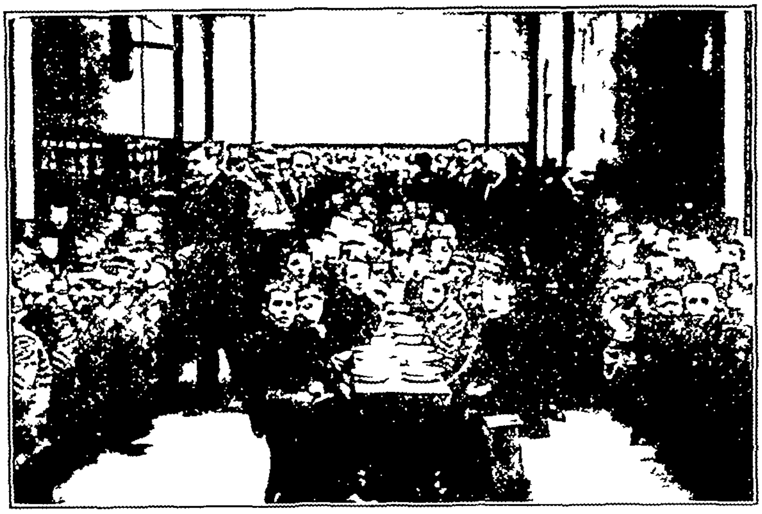

Fig 4—School lunch of the type being inaugurated by the commission throughout Belgium as recommended in this report

Another most significant fact is derived from the maternal canteens for nursing mothers At the beginning of the war the maternal canteens found that the mothers could nurse their infants for a period of nine months, but now, even with supplementary diets in the form of very substantial daily meals, they are barely able to nurse them for seven months, and this in the face of the fact that during the past year expectant mothers have been receiving meals for a period of two or three months before the arrival of the child These facts undoubtedly indicate a lower general health and vitality of the mothers of these classes

DIMINUTION IN BIRTH RATE

As in all warring countries, Belgium has suffered a great diminution in the birth rate This is so significant that it calls for special attention Compared with the average birth rate of the first semester of the five year period 1909-1913, the birth rate has fallen in 1916 in the Agglomeration of Brussels, 48 per cent, in Antwerp, 41 per cent, in Louvain, 41 per cent, in Heverle, 41 per cent, in Namur, 42 per cent, in Mons, 36 per cent, and in Liege, 41 per cent Such are the alarming decreases in all parts of Belgium that some explanation must be sought Probably the lower vitality and mental anxiety have a great deal to do with this lower birth rate Certainly the depopulation of men from Belgium is not in such a proportionate rate as in the other warring countries and not in such proportion as is the reduction in the birth rate However, though there is no general mobilization, the absence of thousands of husbands from the working classes must have something to do with the reduction in the birth rate, further, the lower nutrition in these classes and the fear of not being able to provide for their offspring must be strong factors toward a voluntary reduction

INFANTS AND CHILDREN

I have already covered the condition of children fairly completely in the discussion of tuberculosis There are certain other facts, however, that are of considerable significance Rickets, which is entirely a nutritional condition, has increased very markedly, as is shown from the following figures, derived from one of the large children's clinics in Brussels In the period 1909 to 1913, 4 73 per cent of the children who attended the clinic had rickets, in 1914, 8 per cent, in 1915, 11 4 per cent, and in 1916, 21 3 per cent The diminution in the weight of schoolchildren has already been mentioned

Not every aspect of the health conditions of the children in Belgium, however, is as gloomy as these facts would indicate Infant mortality has fallen since the beginning of the war, and deserves special comment (By infant mortality is meant the deaths of children under 1 year of age on the basis of 1,000 births) In the Agglomeration of Brussels, for the first trimester of 1904 to 1908, there were 124 deaths of infants, on an average, from 0 to 1 year of age for every thousand births, for the first semester of 1916 the infant mortality rate on the same basis was 94, or a reduction of 19 per cent In Namur the infant mortality has dropped from 150, for the period 1911 to 1913, to 84 for the first semester of 1916 In Namur, however, the deaths from 1 to 5 years are the same for the first half of 1916 as they were for the whole of 1915 In Antwerp the infant mortality has dropped 8 per cent, while in Mons, one of the largest industrial centers, infant mortality has increased 56 per cent

In 1915 the deaths from diarrhea in Liege, of children under 2 years of age, were, for the first semester, forty-three, while for the same period of 1916 they were twenty-three, a diminution of 47 per cent In Antwerp the reduction in cases of diarrhea is also marked During the period from 1911 to 1913 there was an average death rate of children under 2 years of age of 749, while during the year 1915, there were only 231 deaths from this cause In the Agglomeration of Brussels we note the same decrease in diarrheal conditions In 1913, during the first semester, there were 219 deaths from diarrhea, in 1914, for the same period, 256, for 1915, 156, and for 1916, 81

PRESENT INSTITUTIONS DIRECTLY FEEDING CHILDREN

It is generally evident that infant conditions are on the whole better than normal, that class having been the object of great solicitude since the beginning of the war A great many institutions have been created during the war to care for the children The organization of the work for the children has been divided into canteens

1 Canteens for nursing and expectant mothers, which, as already stated, furnish a substantial supplementary meal There are over 13,000 nursing and expectant mothers receiving these dinners

2 Canteens, often in conjunction with maternal canteens, have been instituted for infants under 3 years of age in which there are over 52,000 infants receiving milk and cereals Both these types of canteens have undoubtedly had a great influence on the reduction of infant mortality in Belgium There is no question that today, in Belgium, more is being done for the mother and the child than was ever done before Previous to the war there were only two maternal canteens in the whole of Belgium, today there are over 329 canteens for infants These canteens, in connection with the educational work, the medical supervision which all the canteens have, and the careful regulation of the dietary, both in the canteens and, by an extensive system of visiting nurses, in the homes, have undobutedly had a marked effect on this great reduction in infant mortality This phase of the child welfare work in Belgium is one of the best examples of the efficiency and result of the extensive and carefully planned preventive measures which have been instituted throughout Belgium by the relief organization

Besides these canteens for mothers and infants, special canteens have been started to give food, supplemental to the ordinary ration, to debilitated children from 3 to 17 years of age These children are chosen from the poorer sections, after a medical examination, and receive a supplementary dinner Each canteen is under the direct supervision of a medical staff, which not only prescribes the proper dietary but also looks after special health problems A health card is made out for each patient on which the weight is entered from month to month A review of several hundreds of these cards brings out some interesting facts It is generally noted that on admission and for the first two or three months afterward, a large proportion of these debilitated children gain in weight They then reach a stationary period, which lasts for a month or two, and then either stop gaining entirely or lose slightly, so that the average amount gained for a period of a year is considerably below the average amount which children of their respective ages should gain In these canteens over 25,000 children are being fed at the present time Up to July 1, 1916, the age limit was 14 years, since July 1, however, this age limit has been increased to 17 years to make room for the thousands of debilitated, adolescent children who, during this period of rapid growth, a period which requires a larger proportional amount of nutrition than any other period of life, require a supplementary diet It is during this adolescent period that a marked increase in tuberculosis has been noted As is well known, the most fulminating types of tuberculosis are likely to appear during the adolescent period

CONCLUSIONS

It may be said that the present general health situation in Belgium is not a gloomy one, considering the circumstances The well-to-do and agricultural classes are fully up to the normal In the industrial and minor commercial classes, while there is great privation, as the result of relief organization, the adult population is in a position to quickly recover its normal condition, general solicitude for the children has resulted in an actual improvement in infant conditions to a point above the normal, and the measures now being taken to reinforce the care of adolescent children by a further meal in the schools should quickly bring this class up to a state approaching normality With the exception of the increase in tuberculosis, the population has been singularly free from epidemics or contagious diseases, for instance, typhoid fever and the children's contagious diseases have been markedly diminished and, except for the epidemic of grip, which was prevalent last winter and spring, there have been no serious epidemics since the occupation The high degree of skill of the Belgian medical profession, its devotion to the people, and the watchful eye of the army of occupation in the protection of its own interests, with the military restriction of movement of the population, have probably all contributed to this end

The general solicitude of the whole relief organization over the question of health and nutrition has been insistent since its inception, and the magnificent work which has been performed by the women of Belgium, in the care of the child, is beyond praise The maintenance of these measures, both as to nutrition and welfare, by the relief organization, is an absolute and daily necessity to the population The cessation of the commission for relief in its labors, for a single month, would unquestionably bring a physical disaster to the industrial and lower commercial classes

Poor Milk—If poor milk as a commodity of commerce commands the same price as good milk, and is cheaper to produce, we may expect the milk supply to tend to approximate the poorest quality which health officials will allow to be sold—Hon E S Brigham, *Bulletin*, Vermont State Board of Health, Dec 1, 1916

AURAL TYPHOID CARRIERS A REPORT OF TWO CASES

A B BENNETT, M D, WASHINGTON, D C

The usual understanding or definition of typhoid carrier is a person who, though apparently well, has the bacilli of typhoid fever in the stools or urine There have not been many reports of cases in which the typhoid organism has been cultured from other discharges in persons otherwise apparently well Therefore I believe it worth while to report the following cases

CASE 1—B S N, man, white, aged 34, with negative family history, in 1898, while serving in the U S Volunteers in Porto Rico, suffered a severe attack of typhoid fever Ever since then there has been a chronic purulent discharge from the left ear with an occasional acute exacerbation When I saw him, the temperature was 100, the mastoid was tender, there was a free flow of creamy pus from the left external meatus, the inferior posterior half of the left membrana tympani was destroyed, and the patient complained of severe earache and painful mastoid, which were much worse at night

Under simple local treatment the temperature subsided and the pain and tenderness disappeared A culture was taken from the ear, and about ten organisms developed, one of which was culturally typhoid A second culture was made which showed much fewer organisms and the same typhoid organism This germ was tested in the laboratory of the U S Naval Hospital and proved to be typhoid It agglutinated in the presence of the patient's blood, and his opsonic index was zero

I thoroughly cleansed and dried out the ear, and gave the patient five doses of typhoid vaccine There was a decided improvement in his general health and the aural discharge was very slight He then left the city and I have been unable to learn anything of him since

CASE 2—M W, girl, white, single, aged 15, with negative family history, had been "born with heart trouble" At 3 years of age she had diphtheria, at 6 measles, at 7 she had the tonsils and adenoids removed, at 10 she had chickenpox, at 11 scarlatina, and at 12 what her mother told me was typhoid pneumonia, which was probably a frank pneumonia The present illness began one month prior to consulting me when she had an attack of acute purulent otitis media (left) with considerable pain and discharge The discharge continued, and on examination I found the left auditory canal filled with pus There was a perforation of the membrana tympani in the center of the anterior half, and through it projected a small polyp which bled profusely on the slightest manipulation making the use of a snare or forceps almost impossible Several applications of trichloracetic acid reduced the polyp to within the perforation, and the discharge lessened but would not cease A smear from the ear showed a great number of diphtheroid bacilli, gram-negative bacilli, a few *Micrococci catarrhales,* and staphylococci A culture from the ear developed diphtheroid and gram-negative bacilli A vaccine was made and seven doses given, increasing from 50 million to 1,000 million, which resulted in an entire cessation of discharge after the seventh dose The culture was grown and vaccine made by the National Vaccine Laboratory which reported later to me that the gram-negative bacilli proved to be typhoid bacilli

Neither of these patients was under my care very long I was unable to learn of any cases of typhoid that could be traced to contact with these persons, nor was I able to ascertain if they were carriers of typhoid in their urine or stools However, I believe that the isolation of the typhoid bacillus from the middle ear discharge of two patients is worthy of report

---

The Unvaccinated—People have smallpox because they prefer it to vaccination The whole population pays for the privilege of having smallpox monopolized by the unvaccinated—*Bulletin,* Minnesota State Board of Health, December, 1916

Therapeutics

DISTURBANCES OF THE KIDNEYS

(Continued from page 2017)

FAT (LIPURIA)

A minute amount of fat (0 02 gm) is excreted daily This amount may be increased to 34 mg by eating large amounts of fat, according to Sakaguchi[55] He investigated the urinary fat output in various chronic diseases, and found no disturbance of this minute urinary excretion The fat of the urine may, however, be increased in chronic nephritis when there is fatty degeneration of the kidneys, and is probably usually increased in phosphorus poisoning

CHYLURIA

This is a rare condition in which a milky urine is due to chyle entering the urinary canals directly from the thoracic duct Such a condition is generally caused by the burrowing of parasites called filariae An unexplained chyluria has rarely occurred

CYSTINURIA

Cystin rarely appears in the urine Its appearance is due to improper metabolism in the body Cystin is an amino acid derived from protein, and is normally transformed in the body, its sulphur appearing in the urine as a sulphate Infrequently cystinuria causes deposits in the pelvis of the kidney or in the bladder This condition should be treated by a reduction of the amount of protein consumed and by the administration of alkalies Cystin may be produced by the body proteins, and an endogenous cystinuria may sometimes occur

ALBUMOSURIA

Excretion of proteoses in the urine constitutes the condition called albumosuria It may occur in suppurative conditions or processes such as that which takes place during the resolution of a serious pneumonia in which a considerable portion of lung has been involved It has occasionally been found in leukemia

BENCE-JONES PROTEIN

The abnormal protein substance termed Bence-Jones protein is probably of endogenous origin It is generally combined with anemia and does not seem to be a decided symptom of anything, but multiple myeloma or some form of bone-marrow disease The prognosis for this condition is unfavorable

UROBILINURIA

Bilirubin is converted in the intestines by bacterial action into urobilinogen and urobilin, which are absorbed by the blood and converted into bilirubin in the liver Traces are usually found in the urine When an increased amount appears in the urine, the condition is termed urobilinuria

BILIRUBINURIA

Any obstruction of the biliary ducts will cause absorption of bilirubin into the blood, resulting in jaundice, and bilirubinuria The urine becomes brown, and when shaken shows a yellow froth

If bilirubin appears in an increased amount in the urine it denotes a more or less serious liver disturbance If a small amount of this bile substance passes off in the urine it is not harmful to the kidneys, but if a large amount is excreted during an extended period of time, renal irritations, possibly accompanied by albuminuria, may occur

ALBUMINURIA

Albuminuria may be classed as follows

1 *A symptom of nephritis*
2 Accidental albuminuria causes
    (a) Dietary (alimentary)
    (b) Chilling of the body
    (c) Unexplained (frequently due to focal infection)
3 Incidental albuminuria causes
    (a) Cold baths
    (b) Menstruation
    (c) Athletics or other physical strain
    (d) Cardiac weakness
    (e) Irritation in some part of the urinary tract
    (f) Hypertension
    (g) Ether or other anesthesia
4 Orthostatic (lordotic, cyclic, adolescent)

The term "albuminuria" refers to the presence of serum-albumin in the urine Nucleo-albumin may be present occasionally in a patient who is in perfect health Frequently nucleo-albumin and serum-albumin are both present, particularly in acute or subacute nephritis Nucleo-albumin is rarely present in chronic nephritis The presence of this substance alone does not ordinarily mean that there is a kidney lesion Albumin in the urine is either excreted by the kidneys or comes from some part of the urinary passages If it results from some localized irritation, inflammation or hemorrhage, there are more white cells present in the urinary sediment than in ordinary albuminuria If there is hemorrhage, there are, of course, red cells A small amount of albumin is found in cystitis, and a somewhat larger amount in pyelitis The amount, however, is always small unless it comes directly from the kidney secreting substance Urine containing a small quantity of sodium chlorid or other salts may show just a trace of serum-albumin, but if sodium chlorid is added to such urine, a larger deposit will be obtained Frequently urine in which albumin has previously been found becomes free from this substance because the patient is passing a larger total amount of urine, in other words, if he has been given a diuretic or a large amount of water, albumin may not be found, while the same condition which caused the albuminuria still exists Circulatory tonics, such as digitalis, provided the blood pressure is not high, frequently, temporarily at least, may cure an albuminuria

1 The albuminuria of nephritis will be discussed later under that heading

2 Accidental albuminuria may occur from several causes It is sometimes due to exposure to cold, more frequently it is due to some dietary error, such as overloading the system with proteins, or it may be due to some alimentary disturbance Traces of albumin are often found in the urine in intestinal disturbances, particularly in chronic diarrheal conditions Albumin is often found in the urine without any assignable cause, probably owing to some focal infection Mouth and throat infections may cause serious kidney disease, mild irritations, therefore, may cause the appearance of small amounts of albumin in the urine

3 Incidental albuminuria is frequent It may be caused by cold baths or cold showers It may occur with menstruation or when menstruation is delayed It occurs frequently after severe muscle strain, as in competitive athletics

Incidental albuminuria as a symptom of an acute disease, and its appearance during the intensity of an acute infection have been proved Backache and the primary symptoms of most acute infections are probably due to kidney congestion

Cardiac weakness or insufficiency, low blood pressure, or anything which causes congestion of one or both kidneys may allow leakage of albumin On the other hand, a small trace of albumin is frequently a symptom of hypertension, and may be the forerunner of actual kidney disease

Albumin frequently appears in the urine following an operation, and is perhaps chiefly due to the anesthetic It may, however, be due to some position in which the patient is compelled to sustain himself for an extended period of time, such as the lithotomy position, or sluggishness in the circulation of the kidneys may occur from prolonged lying on the back

Renal irritations, or irritations in some part of the urinary tract, frequently cause the discharge of small amounts of albumin in the urine A floating kidney may also be the cause of this condition

When the cause of albuminuria has been determined, the preventive treatment is self-evident If it is a part of some diseased condition, it will diminish with any improvement in that condition

4 Orthostatic albuminuria (lordotic) has also been called the albuminuria of adolescence, because it is apt to occur in developing children As it occurs only when the individual is active, it was for many years supposed to be entirely due to a change in the blood pressure of the kidney vessels, and was termed orthostatic albuminuria, as in the majority of instances the albumin disappeared from the urine if the child remained in bed Occasionally the administration of cardiac tonics and vasopressor drugs improved or prevented the condition This symptom disappeared in many of the children as they grew older, the duration of the condition varying However, since Jehle published his monograph, in 1909, stating that so-called orthostatic and functional albuminuria was often due to lordosis causing passive hyperemia of the kidneys, the truth of his observations has been acknowledged by many investigators It seems probable that some inherent weakness of the kidney circulation must also be a factor, though general vasomotor disturbances and low blood pressure have not been constantly present Not every lordotic person is afflicted with albuminuria, nor is every orthostatic albuminuric lordotic However, lordosis is apparently a frequent cause of albumin in the urine in an active patient

Albuminuria due to lordosis may come from only one kidney, as has often been proved by ureteral catheterization In schoolchildren it may be the result of sitting for some time daily with the hands folded behind the back[56] Albuminuria may also be caused by a movable kidney, due to venous or passive congestion

The term "orthostatic albuminuria" should be limited to that albuminuria without casts which occurs after standing or moving about, and which disappears with a reclining position If casts and blood cells are associated with this condition, the patient may be suffering with nephritis Hence position may be the final cause of sufficient passive congestion for the excretion of albumin, casts and blood cells The necessity for complete rest, in even slight kidney congestion, is therefore obvious

---

[56] Piesen Wien klin Wchnschr Jan 5 1911

Orthostatic albuminuria may be due not only to lordosis, which produces a passive congestion of otherwise normal kidneys, but also to an insufficiency of the kidney circulation, possibly congenital, with or without lordosis This condition may also be caused by kidneys of insufficient size for the individual Orthostatic albuminuria may also be caused by certain positions or labors which cause a profusion of blood to course to the kidneys, resulting in passive congestion and leakage of albumin Sometimes in rapidly growing youths the kidneys may be insufficient, just as we find hearts insufficient Later the kidneys grow to the body size

Lordotic albuminuria or albuminuria due to disturbed circulation in otherwise normal kidneys usually occurs between the ages of 10 and 15 Scoliosis may also be a factor in causing albuminuria Tall, thin children with poor circulation are most frequently affected This insufficiency of circulation is evidenced by cold hands and feet, and general weariness after exercise Functional or orthostatic albuminuria, or albuminuria occurring after hard exercise, may be due to a kidney which has imperfectly recovered from a previous inflammation This kidney may be insufficient for years and become a predisposing cause of chronic nephritis

The prognosis of this albuminuria of adolescence is generally favorable, although it usually shows a lack of kidney tone or imperfect function, and may indicate that the surrounding circulation is not perfect Hence there is danger of serious disturbance later, particularly with any added strain on the kidneys

In intermittent albuminuria, although casts may be absent, there is always the possibility of development into a condition of nephritis, consequently insurance companies look on these cases with suspicion However, patients with intermittent, lordotic or orthostatic albuminuria not infrequently recover completely and permanently

Before an albuminuria is considered a simple albumin leak, all suspicion of more serious conditions of the kidneys must be eliminated by examinations of the urine under varying conditions Casts must be absent, and there must be no cardiac hypertrophy or other symptoms which would show that the kidneys are suffering from localized or general inflammation If granular casts are found, the prognosis is not good, but may not be very bad Determination of the absence of any focal infection, tests of function, blood examinations, and, if advisable, the passage of ureteral catheters to show whether both or only one kidney is at fault will make the prognosis clear

The results of urine examined on first rising in the morning, and again in the latter part of the afternoon will quickly show whether the condition is an orthostatic albuminuria Also, tests of diet and exercise will show the limitations of the kidneys and their ability to sustain effort without leaking albumin

Temperature tests should be made as it is not unusual to find that so-called functional or orthostatic albuminuria is due to the fact that a tuberculous kidney is developing Such a condition may be discovered before pus or blood appears in the urine The localization of an albumin leak in one kidney, with some rise of temperature in the evening, should cause not only the centrifuged sedimented urine to be examined for tubercle bacilli, but also the guinea-pig test to be made

The spine should of course be examined for scoliosis and lordosis, and proper orthopedic treatment should be instituted if either of these conditions is found Also, any faulty position assumed by the child while studying in school or at home, or such as results from lying in a hammock or sleeping in a bed with too weak springs, should be corrected

Disturbed menstrual function in young girls is at times a factor in causing leakage of albumin When normal menstruation occurs spontaneously or as the result of appropriate treatment, such albuminuria ceases

That hard physical exercise may cause albumin and casts to appear in the urine is now too well known to require proof or discussion That a repetition of this condition in athletes may cause no future harm will not be so readily accepted, though Jundell and Fries,[57] after repeatedly examining the urine of 163 athletes after exercise of various kinds, concluded that the kidneys are never permanently injured They did not, however, take into consideration the more or less permanently increased blood pressure caused by such exercise It would seem only logical to believe that albuminuria caused by athletics represents kidney tire or kidney strain, making these organs more susceptible to irritation, and must be as harmful as over-indulgence in improper food, frequent diarrhea, repeated attacks of rapid heart from coffee or other cause, periods of insomnia, etc

In the treatment of such recurrent albuminuria or in the treatment of lordotic albuminuria, strenuous exercise should be forbidden, and all functions of the body should be made as perfect as possible The diet should be properly arranged, a great deal of rest taken, muscle exercises to increase the strength of the back muscles advised, anemia treated by the administration of iron, a weak heart aided by cardiac tonics, constipation relieved, plenty of fresh air prescribed, and sea bathing and cold bathing usually prohibited—every means being used to improve the general condition of the patient

Of course it should be recognized that traces of albumin may be caused by renal concretions A growing child or youth with traces of albumin in the urine, and with low blood pressure may develop pulmonary tuberculosis

A STUDY OF CROSSED TOLERANCE FOR DRUGS

The expression "crossed tolerance" has been employed to designate the altered susceptibility which subjects that have acquired a considerable degree of tolerance for one drug or poison may thereafter exhibit toward another potent substance In certain instances this phenomenon is well recognized A habitual drunkard, tolerant to large doses of alcohol, usually is noticeably resistant to the general anesthetics It is not difficult to understand the occurrence of crossed tolerance in the case of drugs very closely related which act in essentially similar ways on the organism, but as the mechanism of habituation and increased resistance to drugs is little understood in all but a few instances, the more extreme alleged types of crossed tolerance that have been reported have not been subjected to critical consideration To what extent, aside from a few familiar examples, functional habituation, acquired for a particular drug, may also hold for other drugs of somewhat similar action has remained to be determined

Dr H B Myers,[1] the pharmacologist of the Medical School of the University of Oregon, thus indicates some of the problems in this field The pharmacologic action of ether on the central nervous system may be considered to be similar to that of alcohol, since the two act on the same nerve cells in the same direction, and neither has a selective action not shared by the other The pharmacologic similarity, together with the close chemical relationship, would lead one to assume, even in the absence of known facts, that the toleration of alcohol and ether was mutual Similarly a crossed tolerance between chloroform and the closely related chloral hydrate might be assumed With other drugs, however, which may be grouped together because of some ultimate general effect produced, as, for example, sleep, the assumption of a cross tolerance is not so well warranted, nor are facts available to show whether such cross tolerance does occur

Myers[1] has attempted to ascertain whether crossed toleration can be established, first, between such closely related drugs as morphin and methyl and diacetyl morphin, and second, between morphin and other less related depressants of the central nervous system to which the cells become tolerant, as cannabis indica and chloral hydrate Cannabis indica represents drugs not chemically related but sharing in some of the selective actions of morphin, chloral hydrate such depressants as have neither chemical relationship nor selective actions in common

The outcome of these new experiments indicates that a marked crossed tolerance exists to codein and to heroin in dogs habituated to morphin, so far as effects on the respiratory center are concerned A slight crossed tolerance exists between codein and morphin, and between heroin and morphin in regard to their actions on the tissues governing equilibrium No evidence of crossed toleration to cannabis indica or to chloral hydrate exists in dogs tolerant to large amounts of morphin

It thus appears that a crossed tolerance may exist between closely related drugs, but that this tolerance is evidenced only on those functions in which the drugs have a common selective action The results are in harmony with the older belief in the increased resistance of chronic drunkards, in comparison with ordinary persons, to chloroform Alcohol and chloroform act on the same nerve cells in a similar way, and probably induce the same changes in the protoplasm From Myers' study we may conclude that a crossed tolerance involves only those structures on which the drugs exert effects mutually alike

COLD AIR AND PNEUMONIA IN CHILDHOOD

In a presidential address before the American Pediatric Society at Washington a few months ago, Freeman said

> In all the acute infectious diseases I think there is now a general acceptance of the advantage of fresh air, excepting perhaps in measles and scarlet fever In tuberculosis there is now no question of its advantage In pneumonia the results from this treatment have exceeded those from any other method of treatment, including specific treatment with serums and vaccines There are still many men, however, who, while allowing that fresh air is beneficial in an inflammation of the lung, doubt its efficacy in bronchitis, pharyngitis, laryngitis rhinitis and otitis The only reason why such men doubt its efficacy is because they have not sufficiently tried it I have used it in all these conditions and I believe that it is of direct benefit and that it diminishes materially the mortality[1]

Freeman remarks that the supposed production of catarrhal inflammations in adults by exposure to cold air, if it really exists, exists only on account of suggestion The persons affected have been brought up in such fear of fresh air that every infection of the upper air passages to which they succumb is attributed to it Nevertheless, several recent investigations have indicated that we cannot be entirely indifferent to the possible effects of chilling on the organism Studies of the New York State Commission on Ventilation have indicated that respiratory infections of rabbits with *Bacillus bovisepticum* (snuffles) are favored by the chilling of such animals after they have been accustomed to heat, and some of the results indicate that a change from a low to a high external temperature also predisposes to similar infection Although Chodounsky[2] obtained only negative results, the weight of recent experimental evidence favors the view that exposure of the body to cold is favorable to the incidence of acute respiratory disease, and it seems not improbable that the primary seat of this deleterious influence is in the mucous membrane of the upper air passages[3]

---

[1] Myers H B Cross Tolerance Altered Susceptibility to Codein, Heroin Cannabis Indica and Chloral Hydrate in Dogs Having an Acquired Tolerance for Morphine Jour Pharmacol and Exper Therap, 1916 8, 417

[1] Freeman R G Fresh Air in Pediatric Practice Am Jour Dis Child December 1916 p 590

Considerations of the foregoing sort throw a greater burden of proof on the advocates of any extreme cold air therapy It would be unjust to the commendable advocacy of outdoor life to identify this with chilling from undue exposure Nevertheless, open air treatment always harbors possibilities of even unintentional exposure, which becomes particularly serious to those who, like infants, are least able to make known any undue discomfort produced by their environment The cold air treatment of pneumonias in childhood, endorsed by Northrup about ten years ago,[4] was given a scientific basis by the contentions of Howland and Hoobler[5] They asserted that children seriously ill with pneumonia might have a blood pressure somewhat below that expected at their age, and that the symptoms accompanying fatality in this disease were those of vasomotor failure They found that the effect of cold fresh air on patients with active pneumonia was the production of a rise in blood pressure, removal to a warm (65 F) room produced a fall in blood pressure The results were absent or much less striking in convalescents No results were obtained by placing children outdoors in warm weather They concluded, therefore, that the all important factor in the outdoor treatment was cold, and that the rise in blood pressure was brought about by a reflex stimulation of the vasomotor center through the action of the cold air on the skin They also stated that a constant and continuous increase in an abnormally low blood pressure, brought about without exhaustion or bad effects, is of the greatest value This explanation of the beneficial effects of the outdoor treatment was generally accepted

It has been pointed out recently in The Journal[6] that, contrary to the usual belief, the blood pressure and the vasoreflex are not as a rule seriously impaired in pneumonia Morse and Hassman[7] have made a special study of the effect of cold outdoor air on the blood pressure in pneumonia in childhood at the Children's Hospital in Boston From their statistics there appears to be no constant relation between the systolic pressure, the diastolic pressure or the pressure pulse and the severity of the pneumonia or the temperature of the surrounding air, as the rates of both the pulse and the respiration show a tendency to vary directly with the temperature of the surrounding air

We are apparently not justified at present in formulating conclusions as to the effect of the cold air treatment on the mortality of pneumonia in childhood Patients, however, symptomatically seem more comfortable when they are outdoors than when they are in the house At any rate, the impression of those constantly with the patients was that, in general, the children were more comfortable outdoors than in the ward, they coughed less, were quieter, had a better color, and had better appetites outdoors than indoors These were merely impressions, however, and, as Morse and Hassman admit, are of little or no scientific value

DEATHS OF PHYSICIANS IN 1916

During 1916 the deaths of 2,196 physicians in the United States and Canada were noted in The Journal On an estimate of 158,000 physicians, this is equivalent to an annual death rate of 14 08 per thousand For the fourteen previous years the mortality rates were 1915, 15 71, 1914, 14 41, 1913, 14 64, 1912, 14 13, 1911, 15 32, 1910, 16 96, 1909, 16 26, 1908, 17 39, 1907, 16 01, 1906, 17 20, 1905, 16 36, 1904, 17 14, 1903, 13 73, and 1902, 14 74 The average annual mortality for the period from 1902 to 1916, inclusive, was, therefore, 15 61 per thousand

The chief death causes in the order named were senility, heart disease, pneumonia, cerebral hemorrhage, accident, surgical operations and nephritis The age at death varied from 23 to 99, with an average of 59 years, 11 months, 5 days The general average of age at death since 1904 is 59 years, 8 months and 13 days The number of years of practice varied from 1 to 77 years, the average being 33 years, 2 months and 21 days The average for the past thirteen years is 31 years and 29 days

Causes of Death —There were 225 deaths assigned to general diseases, 261 to diseases of the nervous system, 324 to diseases of the circulatory system, 231 to diseases of the respiratory system, 129 to diseases of the digestive system, 105 to diseases of the genitourinary system, 337 to senility, 39 to suicide, 112 to accident, 15 to homicide, and 98 after surgical operations Among the principal assigned causes of death are senility, 337, heart disease, 215, pneumonia, 208, cerebral hemorrhage, 204, accident, 112, operations, 98, nephritis, 72, tuberculosis, 62, carcinoma, 49, appendicitis, 40, suicide, 39, arteriosclerosis, 36, diabetes, 29, angina pectoris, 26, septicemia, 21, uremia, 17, myocarditis, 16, homicide, 15, endocarditis, 14, gastritis and cirrhosis of the liver, each 13, influenza, anemia and cholecystitis, each 12, typhoid fever, 11, gastric ulcer, 10, general paralysis of the insane and paresis, each 9, paralysis, 8, dilatation of the heart, intestinal obstruction and peritonitis, each 7, erysipelas and meningitis, each 6, embolism and disease of the prostate, each 5, typhus fever, sarcoma, pleurisy, asthma and ptomain poisoning, each 4, diphtheria, pericarditis and bronchitis, each 3, malaria, drug addiction, neuritis, anterior poliomyelitis, mastoid disease, duodenal ulcer and dropsy, each 2, and scarlet fever, bubonic plague, yellow fever, epithelioma, Addison's disease, leukemia, alcoholism, tabes dorsalis, Hodgkin's disease, paralysis agitans, Pott's disease, paratyphoid fever, trypanosomiasis, pancreatitis and tumor of the esophagus, each 1 One physician died in prison Ten medical officers lost their lives from wounds received in the European, Asiatic and colonial war zones

[7] Morse J L and Hassman D M The Effect of Cold Air on the Blood Pressure in Pneumonia in Childhood Am Jour Dis Child November, 1916 p 445

The causes assigned for the 112 deaths from accidents were automobile, 28, falls, 18, railway-automobile (grade crossing), 17, railway, 11, drowning, 11, firearms, 7, poisons and burns, each 5, sunstroke, starvation and exposure, and explosions, each 2, and Roentgen-ray burns, crushing and street railway, each 1 The 59 physicians who ended their lives by suicide selected the following methods firearms, 24, poison, 7, hanging, 3, cutting instruments, 2, and other means, 3 Of the 15 homicides, 13 were due to firearms, 1 to cutting instruments, and in 1 the method was not reported

Ages —Of the decedents, 62 were between the ages of 21 and 30, 194 between the ages of 31 and 40, 343 between 41 and 50, 438 between 51 and 60, 499 between 61 and 70, 386 between 71 and 80, 159 between 81 and 90, and 19 between 91 and 99 The greatest mortality occurred at the age of 64, when 68 deaths were recorded

Military Service —During the year 221 physicians died who had served in the Civil War, and of these 54 had followed the fortunes of the Confederacy, 45 had been medical officers of United States Volunteers The Medical Corps of the Army lost 8 officers, 7 had been members of the Medical Reserve Corps, and 17 had been contract or acting assistant surgeons The Navy lost 13 medical officers, the Public Health Service 10 officers, the Indian service 3 physicians, and the organized militia 45 medical officers, of whom 6 had attained the grade of surgeon general

Civil Positions —Of those who died, two had been United States senators, one a member of Congress, one, governor of a state, 6, United States consuls, 13, members of state senates, 32, members of the lower houses of legislatures, 28 had been mayors, 33, aldermen, 33 had served as justices of the peace, as clerks in the government service or in various other civil positions, 7 had been postmasters, 16, editors of medical or lay journals, 27 had also been clergymen, of whom ten were foreign missionaries, 4 had been attorneys, 92, druggists, 40, bankers, 15, medical directors of life insurance companies, 5, dentists, 1, a president of a railway company, 1, a botanist, 1, a musician, 1, a toxicologist, and 8, chemists

Association Fellowship —Of the 596 Fellows of the American Medical Association who died during 1916, seven had been members of the House of Delegates, one, Dr H L E Johnson, had been a member of the Committee on National Legislation, one, Dr Henry B Favill, was chairman of the Council on Health and Public Instruction, five, Drs Wisner E Townsend, Frank J Lutz, William L Rodman, Philip Mills Jones and H L E Johnson, had been members of the Board of Trustees, and two, Drs William L Rodman and John B Murphy, had served as President of the Association

THE REFINEMENT AND CONCENTRATION OF DIPHTHERIA ANTITOXIC SERUMS

The introduction of a practical method for the concentration and refinement of diphtheria antitoxin, devised by Gibson[1] in 1905, marked an important step in advance from a therapeutic standpoint It represented the applications of the experiences of protein chemistry to a problem which is essentially of a biochemical character It consisted in removing a globulin fraction from the serum or plasma and subjecting it to purification by precipitation, solution and dialysis The antitoxic properties of horse serum followed the globulin at every step The expression "antitoxic globulins" thus came into prominence

It had previously been maintained that the artificial concentration of antitoxin is superfluous because it is possible to immunize animals to such a high degree that any further procedure is unnecessary The production of such highly potent serums, however, is attended with much uncertainty and is sometimes exceedingly expensive With the introduction of concentration schemes, citrated plasma could be used instead of serum in the preparation of antitoxic fluids Coagulation is prevented by the citrate — the corpuscles sediment — and the yield of productive plasma is often 50 per cent greater than that of serum obtained by spontaneous clotting of blood Not only has the plan of "concentrating" antitoxin by the methods of protein fractionation permitted the satisfactory use of low grade serum or plasma which would otherwise have been of little value, but it has also established the possibility of eliminating some of the undesirable effects, for example, serum rashes, attending serum injections, by removing by-products presumably responsible for them Finally, a smaller volume of fluid is required for injection

---

[1] Gibson R B The Concentration of Antitoxin for Therapeutic Use *Jour Biol Chem 1905 1906, 1, 161*

From time to time improvements have been made in the preparation of antitoxic protein fractions of the blood of immunized animals, usually based on the separation of the blood proteins in accord with the principles just discussed Urticaria has been reduced in frequency but by no means completely excluded The most recent process was planned by Heinemann[2] at the Serum Division of the Memorial Institute for Infectious Diseases, Chicago It involves a combination of well known methods of precipitation and heating protein solutions, with a persistent repetition of certain details, until the desired results are obtained The precise directions recently published, show that 2,000-unit serum may be produced from plasma testing less than 300 units The apparent stability of the new serum renders it of especial economic value, and a concentrated fluid containing from 18 to 20 per cent of active solids can readily be prepared The higher concentration attainable in comparison with earlier methods is attributed to the more successful removal of nonantitoxic blood proteins The serum disease reactions are reported to be greatly reduced by the use of this new-process antitoxin

We ought to derive a peculiar satisfaction from such reports of progress Not only does this process represent an advance of direct applicability in clinical medicine — it exemplifies the best spirit of scientific endeavor There have been no "secrets" and no veiling of the truth, no patents asked for, and no commercialization in the evolution of the essential methods for producing better antitoxin to combat diphtheria The researches have been published clearly as a gift to all who would use the findings We hear all too little about beneficent scientific philanthropy of this character

---

[2] Heinemann P G The Refinement and Concentration of Antitoxins, Jour Infect Dis 1916 **19**, 433

The Medical Curriculum —With the best possible preparation the medical student finds his daily task quite as much as the strong can carry, and altogether too heavy for the weakling There has been some discussion among medical educators concerning the curriculum, some contending that it is too heavy for the average student This depends on what is meant by the "average student" If the standard set in college work is applied I am of the opinion that medicine does not want such 'average students" I am convinced that a strong student, of high average, can carry the medical work as now imposed and that the imposition of a heavy task succeeds in weeding out the unfit and is therefore desirable We do not develop muscles by lifting feather weights, nor do we strengthen brain activity without earnest effort The aim of medical education is to develop strong men, and in order to do so difficult tasks must be imposed in the training — Victor C Vaughan M D, *Science*, Dec 8 1916

Current Comment

TUMOR CHEMISTRY

From time to time attempts have been made to discover possible chemical differences between the cells of tumors and those of corresponding normal tissues A review of the literature on the subject leaves the impression that if any differences exist they are not sufficiently marked to deserve emphasis[1] Not long ago, however, analyses of malignant tumor tissue by Kocher[2] indicated that this yields a larger proportion of the familiar diamino acid derivatives of the proteins than is found in normal tissues Taken in connection with the demonstrated role of some of the diamino acids, notably lysin, in growth,[3] these facts seemed to offer a new approach to the cancer problem The high content of the diamino acids in the tumors might be looked on as in some way responsible for the abnormal rate of growth of these tissues Drummond,[4] of the Cancer Hospital Research Institute, London, has made new analyses of neoplasms which could be controlled experimentally These furnish a different interpretation to the findings just mentioned The distribution of nitrogen in a large number of the proteins of human and chicken tumors and normal tissues has been examined A higher proportion of the diamino acids generally exists in the case of the tumor proteins It has been shown that in all probability the diamino acid content of a tissue varies directly with the amount of nuclear material present The more rapidly growing and cellular tumors, therefore, show a higher percentage of these substances than do the slowly growing ones As Drummond contends, all the evidence points to the conclusion that the higher percentage of diamino acids which is often present in the proteins of malignant growths is due to the greater proportion of nuclear material which they contain, for similarly high figures for this fraction of the protein molecule are found in the analysis of those normal tissues which possess cells rich in nucleoprotein, as, for example, normal human pancreas and spleen A different explanation of the increased rate of cell division must still be sought

IS PELLAGRA TRANSMISSIBLE?

After reviewing the available evidence of the Robert M Thompson Pellagra Commission regarding the nature of the etiologic factor in pellagra, Vedder[5] wrote in 1914

> I regard the question as to whether pellagra is an infection or a deficiency disease to be entirely open It does not appear to me that any evidence that can be regarded as proof of either hypothesis has yet been presented It is rather a question of weighing the evidence and determining toward which hypothesis the bulk of the evidence points

[5] Vedder E B Dietary Deficiency as the Etiological Factor in Pellagra Arch Int Med August 1916 p 137

The commission has been inclined to believe rather strongly that it points to the infectious origin of the disease It seems to me that so far as I have examined it the evidence points at least as strongly toward a dietary deficiency

Vedder's conclusions were evidently dictated by the similarity between pellagra and other known deficiency diseases, notably beriberi and scurvy Much of the evidence that has been presented as proof of the infectious nature of pellagra can be reasonably explained in accordance with a deficiency hypothesis Since then, Goldberger's studies on the causation and mode of preventing pellagra have added evidence to the belief that this disease rests on some dietary defect, and that relief can be brought about by changing the food of the patients[6] His work is in harmony with the earlier failure of Lavinder and Francis[7] and others of the U S Public Health Service to transmit pellagra to monkeys by inoculation of material from pellagrous lesions To this may now be added the recently reported experimental attempts at transmission of pellagra to the human subject[8] Sixteen volunteers, mostly members of the Public Health Service, were subjected to procedures intended to afford evidence of the communicability of pellagra, in case this was of an infectious nature The materials used were blood, nasopharyngeal secretions, epidermal scales from pellagrous lesions, urine and feces Blood was administered by intramuscular or subcutaneous injection, secretions by application to the mucosa of the nose and nasopharynx, scales and excreta by mouth Both urine and feces were ingested by fifteen of the volunteers, five of whom also took blood, secretions and scales The experiments were performed at four widely separated localities (Washington, D C, Columbia, S C, Spartanburg, S C, and New Orleans), at which different groups of the volunteers were assembled As none of the subjects, during a period of between five and seven months, have developed evidence justifying a diagnosis of pellagra, no support is lent to the belief, still widely held, that pellagra is a communicable disease The epidemiologic features are not incompatible with either hypothesis as to etiology

THE EFFECT OF CHRONIC LEAD POISONING IN THE GERM CELLS OF THE MALE

The effect on the offspring of lead poisoning in the father has long been suspected from statistics on the probability of harmful effects from paternal plumbism in man on the germ cells[9] The suspicions have been justified by the experimental studies of Cole and Bachhuber[10] at the University of Wisconsin, and of Weller[11] at the University of Michigan The results of paternal lead poisoning are not manifested in sterility or stillbirths, but they are exhibited in the offspring by a reduction of approximately 20 per cent in the average birth weight, by an increased number of deaths in the first week of life, and by a general retardation in development such that the offspring of lead-poisoned males often remain permanently underweight One naturally inquires whether the spermatozoa of lead-poisoned males show any detectable changes associated with lead blastophthoria The testes of such individuals have now been examined in sufficient numbers by Weller[12] to permit the statement that in the majority of cases no histologic differences can be detected between the testes of lead-poisoned subjects and those of normal controls Spermatogenesis appears to take place along normal lines and at a rate which seems not unlike that in normal individuals This observation is in no degree incompatible with a state of true blastophthoria, since it is to be expected that, if fertilization takes place at all, the spermatozoa will show no great variation from the normal as far as their appearance is concerned The reason for the inferiority of the offspring is to be sought rather in qualitative changes in the germ plasm In a limited group of instances, in which the male animal became sterile during the administration of lead, histologic examination of the testes showed complete aspermatogenesis with marked atrophy and vacuolar degeneration of the germinal epithelium

THE SEARCH FOR THE IDEAL ANTISEPTIC

The ideal antiseptic procedure obviously would be one which would destroy the infecting micro-organisms but leave undamaged the body cells with which it might come into contact The quest for such a substance has continued with enthusiasm almost since the time of Koch's fundamental researches on chemical disinfectants published thirty-five years ago The substances proposed during this period have been legion They represent the most diverse types of chemical compounds, acting by a variety of reactions, but all resulting in a damage to the bacterial body, whether it be by rapid oxidation, by coagulation of the protoplasm, by dehydration, by chemical combination or by some more subtle process The living body is a structure of living cells comparable in many respects with the inimical micro-organisms The tissue cells, therefore, are likely to experience as much damage from efficient antiseptics as do the invading bacteria Experience teaches what considerations of comparative biology lead one to expect, that in infected wounds, for example, the antiseptic must often be applied in such strength that body cells as well as bacteria are injured or destroyed Nevertheless the search for the ideal has continued in the hope, often seemingly useless and unjustified, of ultimately finding some discriminating agent suitable for bacterial destruction After all, the tissue cells are not identical with the lowest forms of microbiotic structure, or entirely analogous to them One technical difficulty in the planning of investigations has been the lack of suitable isolated body cells which could be observed with respect to the possible effects of antiseptics This has been overcome, however, by the use of so-called tissue cultures in which the growth of isolated connective tissue cells can now easily be watched in the laboratory In this way R A Lambert[1] has followed the effect of the same chemical agents on bacteria and tissue cells growing together in vitro Some estimate of the comparative resistance of body tissues to various antiseptic chemicals should thus be gained It is apparent from his study that in the case of the chemical substances tested, such as potassium cyanid, phenol (carbolic acid), tricresol, hydrogen dioxid and alcohol, tissue cells were definitely more easily killed than were bacteria With certain other disinfectants the difference was not so striking Iodin stands out as the one chemical tested to which cells were found more resistant than were staphylococci A good growth of cells was seen after exposure to a 1 2,000 solution of iodin for an hour, a strength sufficient to sterilize the tissue completely in most instances Lambert points to his experiments as further evidence of the widely accepted value of iodin as an antiseptic They indicate that, at least in weak aqueous solution, it should not, as is often stated, injure or irritate the tissues Lambert is careful to point out, however, that iodin has the power of rapidly dissolving fibrin Ordinarily the union of wound surfaces by the fibrin facilitates healing The use of fibrin-dissolving, but tissue-conserving solutions raises a debatable theoretical question which application in practice can perhaps best decide

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION PUBLIC HEALTH, ETC)

ARKANSAS

Personal—Drs Dee C Lee, Rolland F Darnall and Patrick Murphy have resigned as members of the staff of the State Hospital for Nervous Diseases, Little Rock——Dr Robert B Corney, Little Rock, has been appointed physician to the Tucker Convict Farm

Hospital Activities—The executive committee of the campaign for raising funds for the proposed new City Hospital, Little Rock, announces that it will start a campaign to raise $50 000 which will bring the fund to the desired figure of $200 000——The legislature will be asked to appropriate $187,000 for the work against tuberculosis and for the maintenance of the State Tuberculosis Sanatorium, Booneville, during the next biennium One of the principal improvements suggested is the erection of a building for negroes suffering from tuberculosis, and $5,000 for a children s building

CALIFORNIA

Personal—The resignation of Dr Joseph Henry Catton San Francisco as assistant in medicine on the faculty of the University of California, was accepted by the regents at their last meeting

Supreme Court to Decide—It is reported that P L Crane, a chiropractor, is attempting to have the California medical law declared unconstitutional on the grounds that it exempts one group of practitioners—Christian Scientists—but requires chiropractors to pass an examination The case has been appealed to the United States Supreme Court after having been suspended three different times by the United States District Court

Lectures at Stanford Medical School—A course of popular medical lectures will be given at the Stanford University Medical School, San Francisco, during January, February and March The program for January is as follows

January 12, What Every One Should Know About Cancer' Dr Harry M Sherman representing the American Society for the Control of Cancer

January 26, Modern Efforts to Secure Painless Childbirth ' Dr Frank W Lynch, Professor of Obstetrics and Gynecology, University of California

CONNECTICUT

Smallpox—Waterbury had reported 104 cases of smallpox up to December 19 Compulsory vaccination is being enforced Dr John T Black, secretary of the state board of health is in Waterbury, and has assumed active charge of the situation

State Health Association Organized—At a largely attended meeting of the health officers medical men and others interested in public health held at the Chamber of Commerce in New Haven, December 6, the Connecticut Public Health Association was organized and Dr Stephen J Maher, New Haven, was elected president

Personal—Dr John W Churchman New Haven, who has been on duty at Bar le Duc, France, for several months has arrived home and expects to return to his work on the Western war front in March——Dr Walter H Brown has been placed in charge of the health department of Bridgeport He will reorganize the department and establish a department of vital statistics——Dr James E Hair, Bridgeport, has been injured in an automobile accident

DISTRICT OF COLUMBIA

Medical Society Elects Officers—Officers for 1917 have been elected by the Medical Society of the District of Columbia as follows president, Dr G Wythe Cook vice presidents Drs Charles M Beall and Milton H Prosperi, recording secretary, Dr Henry C Macatee, corresponding secretary, Dr J Lawn Thompson, and treasurer Dr Charles W Franzoni

Medical Committee for Inauguration Day—To safeguard the crowds that will be in Washington to view the parade and take part in other ceremonies attendant on the inauguration of President Wilson on March 5 next 140 of the city s physicians have been organized into a medical committee, of which Dr Phillip S Roy is chairman, and Dr William P Carr, vice chairman

Novel Suit for Damages—A Washington physician and a hospital are named as defendants in a novel suit recently filed The basis of the suit is the quarantining of a rooming house kept by the plaintiffs, in August last on account of smallpox A roomer it is alleged, was taken sick and by direction of the physician was taken to the hospital for treatment After remaining in the hospital four or five days the patient was returned to the rooming house and the case reported to the health officer as possibly smallpox Investigation confirmed the physician's suspicions and the patient was taken to the smallpox hospital and the rooming house quarantined The plaintiffs allege that the physician and the proper authorities at the hospital should have known that the patient had smallpox that the patient was returned to their rooming house without notice to them of the probable nature of his disease, and that they have suffered damage as the result

GEORGIA

New Medical Societies Organized—Physicians of the second district met in Thomasville December 14 and organized the Second District Medical Association, electing Dr Everett Daniel Moultrie president, Dr William J Jennings Thomasville, vice president, and Dr Eric J Newsom, Camilla secretary-treasurer The first regular meeting of the association will be held in Moultrie in February——Physicians of Colquitt County met at Moultrie December 21, and organized the Colquitt County Medical Society, electing Dr William I Jerkins president, Dr J A Summerlin Hartsfield vice president, and Dr William W Massey, Moultrie secretary-treasurer The first regular meeting will be held at Moultrie, February 12

---

[1] Lambert, R A The Comparative Resistance of Bacteria and Human Tissue Cells to Certain Common Antiseptics Jour Exper Med, 1916, 24, 683

New Officers—Georgia Medical Society, of Savannah, December 12 president, Dr Antonio J Waring, vice president, Dr James O Baker and secretary-treasurer, Dr William H Myers, all of Savannah ——Eleventh District Medical Society, at Valdosta president, Dr Quitman Holton, Douglas, vice president, Dr John W Simmons, Brunswick, secretary-treasurer, Dr Frank Bird Valdosta, and councilors, Drs Robert C Woodward, Adel, and Henry C Welchel, Douglas Waycross was selected as the next meeting place ——Third District Medical Association, at its semiannual meeting, at Cordele president Dr Thomas J McArthur, Cordele, vice president Dr Joseph T Stukes, Americus, and secretary, Dr Charles A Greer Oglethorpe Americus was selected as the next place of meeting

ILLINOIS

Paris Protects Against Smallpox—Mayor Hoff of Paris issued an order, December 26 that every one coming into Paris from Terre Haute, Ind where smallpox exists, should be vaccinated

Sanitary Survey of Quincy—The city council of Quincy has invited the U S Public Health Service to conduct a sanitary survey of Quincy in cooperation with the state board of health

Vote on Sanatorium Declared Illegal—Attorney General Lucey is said to have decided that the special election held in Aurora last month in which the supervisoors of Kane County were authorized to appropriate money for a tuberculosis sanatorium, was illegal, because of incorrect wording of the ballot

Personal—Dr Marguerite D Mitchell Macdougall Aurora was found semiconscious, almost frozen, and seriously injured in the rear of her home in Aurora December 31 She states that she slipped and fell from the window but her husband is reported to be in jail in Aurora charged with assault with intent to kill

Health News—The November number of *Health News,* the official monthly bulletin of the Illinois State Board of Health, is devoted chiefly to poliomyelitis, one paper being on the orthopedic after-care of paralysis victims another on the diagnosis which is a thorough presentation of the subject, and a third on recent developments in poliomyelitis which presents some general considerations of the subject in an interesting manner

Vaccination Ruling Upheld—The campaign of the Illinois State Board of Health to exclude unvaccinated children from schools, during an epidemic of smallpox, has been upheld by a decision of Master in Chancery E H Marsh of Rockford An injunction had been asked against the Rockford Board of Education, which had directed the exclusion from schools of unvaccinated children, as required by the ordinance The master in chancery held that the ordinance was valid and refused to grant the injunction

Contagious Disease Hospital—The city council finance committee, on December 29 authorized Health Commissioner Robertson to make habitable the new contagious disease hospital and appropriated $10,000 for this purpose The building has been completed since November 28, but no appropriation had been available for its equipment It is reported that the hospital will be ready to receive patients, January 8 It is probable that the hospital will be known as the Alfred C Cotton Hospital ——At a meeting of the Chicago Woman's Club, December 31, addresses were made by Health Commissioner Robertson, Drs Willis O Nance, William R Cubbins, William K Murray, Daniel A K Steele, William A Noble and A Augustus O Neil and it was voted to cooperate with the health department in protecting the children of the city from contagious diseases

Venereal Disease Prevention—At a meeting held December 14 at the City Club under the auspices of the American Social Hygiene Association a movement was inaugurated to rid Chicago of social disease The crusade is to be based purely on scientific principles and will be begun when a committee of volunteer social workers and physicians has been formed Clinics will be established in various sections of Chicago ——Favorable action on an ordinance providing for reporting of venereal diseases without the name of the patient being disclosed was advocated before the city council committee on health, December 26, by Rev John P Brushingham, secretary of the morals committee Addresses in favor of the ordinance were made by Drs Roy R Ferguson, Hugo E Betz, James A Clark Eugene H Wunderlich and Prof Herbert L Willett

Chicago

Hospital to Be Reopened—A meeting to consider plans for the reopening of Maimonides Hospital was held at the Hebrew Institute, December 12, and Drs Jacob Frank, Victor L Schrager and others delivered addresses Funds are being raised rapidly to meet the mortgage on this building, which will enable it to be reopened

Sister Mary Raphael Dies—Sister Mary Raphael McGill, for thirty-five years on duty at Mercy Hospital, and known to thousands of medical students and practitioners of the city, died December 24 At the funeral services, interns of the hospital were active pallbearers, and members of the staff served as honorary pallbearers

Personal—Dr Conrad G Appelle, an intern in the Cook County Hospital, is reported to be seriously ill with typhoid fever ——Dr Charles F Yerger, Cicero, who has been seriously ill for two months from septicemia, secondary to a tonsillar infection, is convalescent ——Major Daniel W Rogers, M C, Ill N G, assigned Seventh Infantry, has resigned, and has been succeeded by Major Eugene G Clancey

Defective Children—The special committee appointed to consider means for providing for physically defective children held a meeting, December 17, at which Health Commissioner Robertson stated that 86,000 children had been examined, that of these 12,000 had defective vision, 1 800, defective hearing, 6,215 diseased nasal organs, 29,642, enlarged tonsils 14,652, adenoids, and 14,044 children had both enlarged tonsils and adenoids

KENTUCKY

Trachoma—Thirty-one mild cases of trachoma were discovered at Bowling Green in three schools comprising 870 pupils This is said to be a smaller percentage of cases than in the schools of other towns of equal size in the state The examinations were made by Dr John McMullen, Lexington government trachoma expert

Louisville Physicians Elect Officers—At the annual meeting of the Jefferson County Medical Society held in Louisville December 18 the following officers were elected president Dr Granville S Hanes, vice presidents, Drs Elmer L Henderson and Joshua B Lukins, secretary, Dr W Hamilton Long, and treasurer, Dr Frank H Ritter

Health Officers' School—The school of county and city health officers of Kentucky held a three-day session in Louisville, December 13 to 16 under the auspices of the state board of health Asst Surg Gen John W Trask, U S P H S, spoke on birth and death reports and Dr John F Anderson, formerly U S P H S, and Asst Surg Lewis R Thompson U S P H S, spoke on various phases of the anterior poliomyelitis situation Dr John G South, Frankfort presided over the conference

Personal—Dr Luther D Nichols, Hickman, was injured in an automobile accident, recently ——Dr J C Sullivan, Dublin, has been appointed first assistant physician at the Eastern State Hospital Lexington to fill the vacancy caused by the appointment of Dr Squire L Helm as superintendent of the Institute for the Care of Feebleminded Children, Lexington ——Dr Eldridge L Bushby Henderson, has been appointed second assistant physician to the Eastern State Hospital, Lexington

Decision on Pollution of Streams—At Princeton, suit was brought against the city for damages on account of pollution of a stream by city sewage, and also asking an injunction against the city enjoining it from discharging sewage into the stream The circuit court granted the injunction and awarded $2,500 damages The court of appeals affirmed the judgment for damages but dismissed the injunction on the ground that the evidence showed that the sewage could be discharged into the stream in such a way as not seriously to injure property owners below the sewer outlet

LOUISIANA

New Armory Opened—The Medical Department of the Louisiana National Guard formally opened its new armory in New Orleans, December 7

New Officers—At the annual meeting of the Orleans Parish Medical Society, in New Orleans, December 19, the following officers were elected Dr Paul J Gelpi, president, Drs Frank J Chalaran, J George Dempsey and Hector E Bernadas, vice presidents, and Dr Henry W E Walther, treasurer

Personal—Charles J Ball, special inspector for the New Orleans Board of Health, has been appointed superintendent of the Hospital for Contagious Diseases, recently opened in that city——Dr John A Devron, New Orleans, has been elected major in the Medical Corps of the Louisiana National Guard——Dr William T O'Reilly has been reappointed health commissioner of New Orleans, and Dr William H Robin, secretary of the City Board of Health

Adopts Higher Requirement—At the meeting of the Louisiana State Board of Medical Examiners, Dec 1, 1916 a resolution was adopted providing that beginning with the session of 1918 1919 no medical school or college will be considered in good standing that does not require for admission at least two years of work in an approved college of arts and sciences This makes seventeen states in which the licensing boards have adopted the two-year standard

Ragweed and Hay-Fever—The New Orleans directorate of the American Hay-Fever Association will ask the legislature at its coming session for legislation for the eradication of ragweed near the city, believed to be the cause of the fall epidemic of hay-fever Enforcement of ordinances of the city concerning weeds has practically eliminated the spring epidemic Examinations of the air on windy days made by the association during the early fall disclosed much ragweed pollen, which was traced to its source outside the city

MARYLAND

Books Left to College—By the will of Dr Holliday Hicks Hayden Baltimore his medical library is left to the College of Physicians and Surgeons

Personal—Dr John F Hogan superintendent of Sydenham Hospital, has been appointed second assistant commissioner of health of Baltimore He will have charge of the Division of Communicable Diseases which will include the work of the health wardens and the department nurses——Dr William R. Geraghty, St Joseph's Hospital, Baltimore has been appointed by the police board department examiner of women and female children to succeed Dr Henry J Walton, Baltimore, resigned——Health Commissioner Blake has announced the appointment of Dr Chester P Woodward as inspector of pasteurization, created by the ordinance of estimates for 1917 in anticipation of the passage of the pure milk ordinance now before the city council——Dr George H Hocking, Govans a member of the State Lunacy Commission, was shot recently and seriously injured by a patient who had suddenly become violently insane

Free Water for Hospitals—The Baltimore Hospital Conference Association has taken up the question of the city supplying the hospitals with free water and removing ashes Water bills vary from $693 for the University Hospital to $3 504 for the Johns Hopkins Hospital In the case of the Hebrew Hospital, exemption from these charges would give $1,300 more annual income In the case of the University Hospital, it would be equivalent to an addition of about $1,000 to their annual income In the case of the Johns Hopkins Hospital it would probably mean between $4 000 and $5,000 a year added to their funds Each of these institutions treats a large number of persons without charge—31 per cent of all the patients at the University Hospital, 50 per cent at the Hebrew Hospital, 64 per cent at St Joseph's Hospital There are 225 000 patients treated free each year in the dispensaries of the hospitals forming the association The association feels that if hospitals are big enough to do this great public work, the city should do its share by furnishing free water and removing ashes

MASSACHUSETTS

Osteopaths' Offer Declined—Osteopaths recently offered to establish a clinic for infantile paralysis patients in connection with the Boston City Hospital The hospital trustees declined the offer and Superintendent Dowling stated that 'the hospital was already prepared to do all that could be done for infantile paralysis patients '

Harvard Medical Lectures.—The faculty of medicine of Harvard University offers this year, as usual, a course of free public lectures to be given at the Medical School Longwood Avenue on Sunday afternoons at 4 o'clock, from January 7 to April 22 inclusive The program for January is as follows

January 7—Rev Dr Francis G Peabody Alcohol and Efficiency

January 14—Dr Hugh Cabot The Care of the Wounded with the British Expeditionary Force in France

January 21—Dr E W Taylor Infantile Paralysis Precautions Necessary and Unnecessary

January 28—Dr W T Porter Shock in the Trenches

Personal—Dr Frankwood E Williams has resigned as chairman of the Massachusetts Advisory Prison Board and executive secretary of the Massachusetts Society of Mental Hygiene, to accept an appointment as associate medical director for the National Committee for Mental Hygiene and editor of the new quarterly magazine which will deal with mental health He will also be in charge of the educational work of mental hygiene throughout the country——Drs Hermon C Bumpus Frank C Richardson, F W Anthony Allen J McLaughlin Milton J Rosenau, Walter E Fernald and George M Kline have been elected directors of the Massachusetts Society for Mental Hygiene——Dr Henry S Rowen, Brighton has succeeded Dr Francis J Keany, deceased, as a trustee of the Boston State Hospital——Dr Hiram Amrial has been appointed assistant physician of the Boston City Hospital

MINNESOTA

Hospital News—St Elizabeth's Hospital, Wabasha is to be enlarged by the building of an "L" of the same height as the main building——The Martha G Ripley Memorial Hospital, adjoining the Maternity Hospital, Minneapolis was dedicated December 9 The dedicatory address was delivered by Rev Franklin W Sweet

Sanatorium Notes—The Wabasha County Tuberculosis Sanatorium, Buena Vista, was formally opened, December 19——Clay-Becker Counties Sanatorium Lake Park was opened with elaborate ceremony, December 3 The institution which has been constructed at a cost of $20,000, will accommodate thirty-two patients

The Study of Health Problems—A combination of all the health activities of Minneapolis under one nonpolitical board was discussed December 18, at a meeting of the committee organized in April by the city council The medical members of this committee are Dr Arthur E Benjamin as representative of the Board of Charities and Correction, and Drs Charles F Dight and Jonas M Kistler, representing the city council

Personal—Dr Francis H. Gambell, mayor of Thief River Falls, has been appointed chairman of the Committee on Public Health of the Minnesota League of Municipalities——Dr Wilhelm S Anderson, Thief River Falls, has resigned as president of the Tri-County Tuberculosis Sanatorium Commission——Dr John Sinclair Redwood Falls, is said to be under treatment in the Redwood Falls Hospital——Drs John G Cross and Thomas B Hartzell are the members of the committee to draft an ordinance for the reorganization of the Minneapolis Health Department——Dr Ralph M Thurlow has resigned as a member of the staff of the Fergus Falls State Hospital

MONTANA

Personal—Dr Frederick M Poindexter, Dillon, sailed from New York December 9, to enter the Red Cross Service in France——Dr and Mrs James E Elliott, Bozeman, have moved to Polson

New Hospitals—Deer Lodge is to have a new hospital to cost $85,000 and to be managed by Catholic sisters——The work on the new Sister s Hospital, Miles City, is almost completed and it is expected that the hospital will be opened early in the year

New Officers—At the annual meeting of the Silver Bow Medical Society held at Butte December 12, the following officers were elected president Dr Arthur C Jones, vice president Dr Joseph F Borghoff, secretary, Dr Spies V Wilking and treasurer, Dr Harold Schwartz, all of Butte

NEW MEXICO

Sanatoriums Consolidated—The Cipes Tuberculosis Sanatorium and the Methodist Deaconess Hospital Albuquerque have been consolidated under the name of the Methodist Sanatorium The institution has a capacity of fifty patients and is under the control of the Home Missionary Society of the Methodist Episcopal Church

New Officers—At the annual meeting of the Bernalillo County Medical Association held in Albuquerque December 7 the following officers were elected president Dr Joseph S Cipes, vice presidents Drs Forrest F Fadely and Oliver T Hyde, secretary Dr Frank E Tull and treasurer, Dr Sylvester G Von Almen, all of Albuquerque

NEW YORK

Personal—Dr James A McMorrow, Syracuse, is ill with appendicitis at the Crouse-Irving Hospital treasurer The first regular meeting will be held at Moultrie, February 12

New Officers—Georgia Medical Society, of Savannah, December 12 president, Dr Antonio J Waring, vice president Dr James O Baker and secretary-treasurer Dr William H Myers, all of Savannah——Eleventh District Medical Society at Valdosta president, Dr Quitman Holton, Douglas, vice president, Dr John W Simmons, Brunswick, secretary-treasurer Dr Frank Bird, Valdosta, and councilors, Drs Robert C Woodward, Adel, and Henry C Welchel, Douglas Waycross was selected as the next meeting place——Third District Medical Association, at its semiannual meeting, at Cordele president, Dr Thomas J McArthur, Cordele, vice president Dr Joseph T Stukes, Americus, and secretary, Dr Charles A Greer, Oglethorpe Americus was selected as the next place of meeting

ILLINOIS

Paris Protects Against Smallpox—Mayor Hoff of Paris issued an order, December 26, that every one coming into Paris from Terre Haute, Ind, where smallpox exists should be vaccinated

Sanitary Survey of Quincy—The city council of Quincy has invited the U S Public Health Service to conduct a sanitary survey of Quincy in cooperation with the state board of health

Vote on Sanatorium Declared Illegal—Attorney General Lucey is said to have decided that the special election held in Aurora last month in which the supervisoors of Kane County were authorized to appropriate money for a tuberculosis sanatorium, was illegal, because of incorrect wording of the ballot

Personal—Dr Marguerite D Mitchell Macdougall, Aurora was found semiconscious almost frozen and seriously injured in the rear of her home, in Aurora, December 31 She states that she slipped and fell from the window but her husband is reported to be in jail in Aurora charged with assault with intent to kill

Health News—The November number of *Health News* the official monthly bulletin of the Illinois State Board of Health is devoted chiefly to poliomyelitis one paper being on the orthopedic after-care of paralysis victims another on the diagnosis which is a thorough presentation of the subject, and a third on recent developments in poliomyelitis which presents some general considerations of the subject in an *interesting manner*

Vaccination Ruling Upheld—The campaign of the Illinois State Board of Health to exclude unvaccinated children from schools, during an epidemic of smallpox has been upheld by a decision of Master in Chancery E H Marsh of Rockford An injunction had been asked against the Rockford Board of Education which had directed the exclusion from schools of unvaccinated children as required by the ordinance The master in chancery held that the ordinance was valid and refused to grant the injunction

Contagious Disease Hospital—The city council finance committee, on December 29, authorized Health Commissioner Robertson to make habitable the new contagious disease hospital and appropriated $10 000 for this purpose The building has been completed since November 28, but no appropriation had been available for its equipment It is reported that the hospital will be ready to receive patients, January 8 It is probable that the hospital will be known as the Alfred C Cotton Hospital——At a meeting of the Chicago Woman's Club, December 31, addresses were made by Health Commissioner Robertson, Drs Willis O Nance, William R Cubbins, William K Murray, Daniel A K Steele, William A Noble and A Augustus O Neil and it was voted to cooperate with the health department in protecting the children of the city from contagious diseases

Venereal Disease Prevention—At a meeting held December 14 at the City Club under the auspices of the American Social Hygiene Association a movement was inaugurated to rid Chicago of social disease The crusade is to be based purely on scientific principles and will be begun when a committee of volunteer social workers and physicians has been formed Clinics will be established in various sections of Chicago——Favorable action on an ordinance providing for reporting of venereal diseases without the name of the patient being disclosed was advocated before the city council committee on health December 26, by Rev John P Brushingham, secretary of the morals committee Addresses in favor of the ordinance were made by Drs Roy R Ferguson, Hugo E Betz, James A Clark, Eugene H Wunderlich and Prof Herbert L Willett

Chicago

Hospital to Be Reopened—A meeting to consider plans for the reopening of Maimonides Hospital was held at the Hebrew Institute, December 12, and Drs Jacob Frank, Victor L Schrager and others delivered addresses Funds are being raised rapidly to meet the mortgage on this building, which will enable it to be reopened

Sister Mary Raphael Dies—Sister Mary Raphael McGill, for thirty-five years on duty at Mercy Hospital, and known to thousands of medical students and practitioners of the city, died December 24 At the funeral services, interns of the hospital were active pallbearers, and members of the staff served as honorary pallbearers

Personal—Dr Conrad G Appelle, an intern in the Cook County Hospital, is reported to be seriously ill with typhoid fever——Dr Charles F Yerger, Cicero, who has been seriously ill for two months from septicemia secondary to a tonsillar infection is convalescent——Major Daniel W Rogers, M C, Ill N G, assigned Seventh Infantry, has resigned, and has been succeeded by Major Eugene G Clancey

Defective Children—The special committee appointed to consider means for providing for physically defective children held a meeting, December 17, at which Health Commissioner Robertson stated that 86,000 children had been examined, that of these 12,000 had defective vision, 1 800, defective hearing, 6 215, diseased nasal organs, 29,642, enlarged tonsils, 14 652, adenoids, and 14,044 children had both enlarged tonsils and adenoids

KENTUCKY

Trachoma—Thirty-one mild cases of trachoma were discovered at Bowling Green in three schools comprising 870 *pupils This is said to be a smaller percentage of cases* than in the schools of other towns of equal size in the state The examinations were made by Dr John McMullen, Lexington government trachoma expert

Louisville Physicians Elect Officers—At the annual meeting of the Jefferson County Medical Society held in Louisville December 18, the following officers were elected president, Dr Granville S Hanes, vice presidents, Drs Elmer L Henderson and Joshua B Lukins, secretary, Dr W Hamilton Long and treasurer, Dr Frank H Ritter

Health Officers' School—The school of county and city health officers of Kentucky held a three-day session in Louisville, December 13 to 16, under the auspices of the state board of health Asst Surg Gen John W Trask U S P H S spoke on birth and death reports and Dr John F Anderson formerly U S P H S, and Asst Surg Lewis R Thompson U S P H S, spoke on various phases of the anterior poliomyelitis situation Dr John G South, Frankfort, presided over the conference

Personal—Dr Luther D Nichols, Hickman, was injured in an automobile accident, recently——Dr J C Sullivan, Dublin, has been appointed first assistant physician at the Eastern State Hospital, Lexington, to fill the vacancy caused by the appointment of Dr Squire L Helm as superintendent of the Institute for the Care of Feebleminded Children, Lexington——Dr Eldridge L Bushby, Henderson, has been appointed second assistant physician to the Eastern State Hospital, Lexington

Decision on Pollution of Streams—At Princeton, suit was brought against the city for damages on account of pollution of a stream by city sewage, and also asking an injunction against the city enjoining it from discharging sewage into the stream The circuit court granted the injunction and awarded $2,500 damages The court of appeals affirmed the judgment for damages but dismissed the injunction on the ground that the evidence showed that the sewage could be discharged into the stream in such a way as not seriously to injure property owners below the sewer outlet

LOUISIANA

New Armory Opened—The Medical Department of the Louisiana National Guard formally opened its new armory in New Orleans, December 7

New Officers—At the annual meeting of the Orleans Parish Medical Society, in New Orleans, December 19, the following officers were elected Dr Paul J Gelpi, president, Drs Frank J Chalaran, J George Dempsey and Hector E Bernadas, vice presidents, and Dr Henry W E Walther, treasurer

Personal.—Charles J Ball, special inspector for the New Orleans Board of Health, has been appointed superintendent of the Hospital for Contagious Diseases, recently opened in that city——Dr John A Devron, New Orleans, has been elected major in the Medical Corps of the Louisiana National Guard——Dr William T O'Reilly has been reappointed health commissioner of New Orleans, and Dr William H Robin, secretary of the City Board of Health

Adopts Higher Requirement—At the meeting of the Louisiana State Board of Medical Examiners, Dec 1, 1916 a resolution was adopted providing that beginning with the session of 1918-1919 no medical school or college will be considered in good standing that does not require for admission at least two years of work in an approved college of arts and sciences This makes seventeen states in which the licensing boards have adopted the two-year standard

Ragweed and Hay-Fever—The New Orleans directorate of the American Hay-Fever Association will ask the legislature at its coming session for legislation for the eradication of ragweed near the city, believed to be the cause of the fall epidemic of hay-fever Enforcement of ordinances of the city concerning weeds has practically eliminated the spring epidemic Examinations of the air on windy days made by the association during the early fall disclosed much ragweed pollen, which was traced to its source outside the city

MARYLAND

Books Left to College—By the will of Dr Holliday Hicks Hayden, Baltimore, his medical library is left to the College of Physicians and Surgeons

Personal—Dr John F Hogan, superintendent of Sydenham Hospital, has been appointed second assistant commissioner of health of Baltimore He will have charge of the Division of Communicable Diseases which will include the work of the health wardens and the department nurses——Dr William R. Geraghty, St. Joseph's Hospital, Baltimore has been appointed by the police board department examiner of women and female children to succeed Dr Henry J Walton, Baltimore, resigned——Health Commissioner Blake has announced the appointment of Dr Chester P Woodward as inspector of pasteurization, created by the ordinance of estimates for 1917 in anticipation of the passage of the pure milk ordinance now before the city council——Dr George H Hocking, Govans, a member of the State Lunacy Commission, was shot recently and seriously injured by a patient who had suddenly become violently insane

Free Water for Hospitals—The Baltimore Hospital Conference Association has taken up the question of the city supplying the hospitals with free water and removing ashes Water bills vary from $693 for the University Hospital to $3 504 for the Johns Hopkins Hospital In the case of the Hebrew Hospital, exemption from these charges would give $1,300 more annual income In the case of the University Hospital it would be equivalent to an addition of about $1 000 to their annual income In the case of the Johns Hopkins Hospital it would probably mean between $4 000 and $5 000 a year added to their funds Each of these institutions treats a large number of persons without charge—31 per cent of all the patients at the University Hospital, 50 per cent at the Hebrew Hospital, 64 per cent at St Joseph's Hospital There are 225,000 patients treated free each year in the dispensaries of the hospitals forming the association The association feels that if hospitals are big enough to do this great public work, the city should do its share by furnishing free water and removing ashes

MASSACHUSETTS

Osteopaths' Offer Declined—Osteopaths recently offered to establish a clinic for infantile paralysis patients in connection with the Boston City Hospital The hospital trustees declined the offer and Superintendent Dowling stated that 'the hospital was already prepared to do all that could be done for infantile paralysis patients'

Harvard Medical Lectures.—The faculty of medicine of Harvard University offers this year, as usual a course of free public lectures to be given at the Medical School Longwood Avenue on Sunday afternoons at 4 o'clock from January 7 to April 22 inclusive The program for January is as follows

January 7—Rev Dr Francis G Peabody Alcohol and Efficiency

January 14—Dr Hugh Cabot The Care of the Wounded with the British Expeditionary Force in France

January 21—Dr E W Taylor Infantile Paralysis Precautions Necessary and Unnecessary

January 28—Dr W T Porter Shock in the Trenche

Personal—Dr Frankwood E Williams has resigned as chairman of the Massachusetts Advisory Prison Board and executive secretary of the Massachusetts Society of Mental Hygiene, to accept an appointment as associate medical director for the National Committee for Mental Hygiene and editor of the new quarterly magazine which will deal with mental health He will also be in charge of the educational work of mental hygiene throughout the country——Drs Hermon C Bumpus Frank C Richardson, F W Anthony, Allen J McLaughlin Milton J Rosenau, Walter E Fernald and George M Kline have been elected directors of the Massachusetts Society for Mental Hygiene——Dr Henry S Rowen, Brighton has succeeded Dr Francis J Keany deceased as a trustee of the Boston State Hospital——Dr Hiram Amrial has been appointed assistant physician of the Boston City Hospital

MINNESOTA

Hospital News—St Elizabeth's Hospital Wabasha is to be enlarged by the building of an 'L" of the same height as the main building——The Martha G Ripley Memorial Hospital adjoining the Maternity Hospital, Minneapolis was dedicated, December 9 The dedicatory address was delivered by Rev Franklin W Sweet

Sanatorium Notes—The Wabasha County Tuberculosis Sanatorium, Buena Vista, was formally opened, December 19——Clay-Becker Counties Sanatorium Lake Park, was opened with elaborate ceremony, December 3 The institution which has been constructed at a cost of $20,000, will accommodate thirty-two patients

The Study of Health Problems—A combination of all the health activities of Minneapolis under one nonpolitical board was discussed, December 18, at a meeting of the committee organized in April by the city council The medical members of this committee are Dr Arthur E Benjamin, as representative of the Board of Charities and Correction and Drs Charles F Dight and Jonas M Kistler, representing the city council

Personal—Dr Francis H. Gambell, mayor of Thief River Falls has been appointed chairman of the Committee on Public Health of the Minnesota League of Municipalities——Dr Wilhelm S Anderson Thief River Falls, has resigned as president of the Tri-County Tuberculosis Sanatorium Commission——Dr John Sinclair, Redwood Falls, is said to be under treatment in the Redwood Falls Hospital——Drs John G Cross and Thomas B Hartzell are the members of the committee to draft an ordinance for the reorganization of the Minneapolis Health Department——Dr Ralph M Thurlow has resigned as a member of the staff of the Fergus Falls State Hospital

MONTANA

Personal—Dr Frederick M Poindexter, Dillon, sailed from New York December 9 to enter the Red Cross Service in France——Dr and Mrs James E Elliott, Bozeman, have moved to Polson

New Hospitals—Deer Lodge is to have a new hospital to cost $85,000 and to be managed by Catholic sisters——The work on the new Sister's Hospital Miles City, is almost completed and it is expected that the hospital will be opened early in the year

New Officers—At the annual meeting of the Silver Bow Medical Society, held at Butte, December 12 the following officers were elected president Dr Arthur C Jones, vice president Dr Joseph F Borghoff, secretary, Dr Spies V Wilking and treasurer, Dr Harold Schwartz, all of Butte

NEW MEXICO

Sanatoriums Consolidated—The Cipes Tuberculosis Sanatorium and the Methodist Deaconess Hospital Albuquerque have been consolidated under the name of the Methodist Sanatorium The institution has a capacity of fifty patients, and is under the control of the Home Missionary Society of the Methodist Episcopal Church

New Officers—At the annual meeting of the Bernalillo County Medical Association held in Albuquerque December 7 the following officers were elected president Dr Joseph S Cipes, vice presidents Drs Forrest F Fadely and Oliver T Hyde, secretary Dr Frank E Tull and treasurer, Dr Sylvester G Von Almen, all of Albuquerque

NEW YORK

Personal—Dr James A McMorrow, Syracuse, is ill with appendicitis at the Crouse-Irving Hospital

New York City

Birth Control Rejected — The Medical Society of the County of New York at its meeting, December 26, by a vote of 210 to 72, voted against any change in the law which would permit physicians to advise married couples as to methods of birth control

Fined for Selling Impure Drugs — A health department inspector recently purchased sodium salicylate from a drug store which on analysis proved to be only 15 per cent pure The magistrate in the municipal term court imposed a sentence on the druggist of $500 fine or thirty days in jail

Harvey Society Lecture — The next Harvey Society lecture will be given at the New York Academy of Medicine on the evening of Jan 13 1917 At this time Prof E V McCollum of the University of Wisconsin will lecture on "The Supplementary Dietary Relationships Among Our Natural Food Stuffs"

Increase in Street Accidents in 1916 — The figures compiled by the Bureau of Records of the Department of Health show that for the first eleven months of 1916 there were nearly 18 per cent more deaths due to street vehicles and surface cars than in the corresponding period of 1916 In 1915 street vehicles were responsible for 453 deaths, in 1916, for 529 Electric cars were responsible for 77 fatalities in 1915 and for 96 in 1916 Falls on the sidewalks or streets caused 50 deaths during the first eleven months of 1915 against 81 for 1916 Falls from wagons cars etc, caused 46 deaths in 1915 and 59 in 1916 That there should be this increase in the number of accidents in view of the large amount of safety-first" educational work and the improved traffic regulations is regarded as remarkable and as indicating the need of still greater efforts in this direction

NORTH CAROLINA

District Society Meeting — At the annual meeting of the Seventh District Medical Society held in Monroe December 5 the following officers were elected president, Dr Henry D Stewart, Monroe, vice president Dr William F Mitchell Shelby, and secretary Dr Silas R Thompson, Charlotte It was decided to hold the next meeting at Shelby on the second Tuesday of October 1917

High Birth Rate — The official records of the registration of vital statistics for the first eleven months of 1916 show 76,704 births, 31,776 deaths and 7 104 stillbirths This is equivalent to a death rate of 13 4 and a birth rate of 32 2 per thousand During the same period thirty convictions were secured for failure to make reports of births, and fines amounting to $115 98 were imposed

Personal — Dr Herbert A Codington has resigned as superintendent of the James Walker Memorial Hospital Wilmington to enter into private practice in that city——Dr Joel D Whitaker Raleigh sustained a fracture of the leg in an automobile accident at Indianapolis several weeks ago, and will not be able to resume practice as early as expected, as it has been necessary to refracture the leg

OHIO

Personal — Dr Charles C Moffett Elyria, is in a critical condition from cerebral hemorrhage——Dr John E Monger, Greenville, is reported to have accepted the appointment of registrar of vital statistics under the state board of health

Chiropractor Prosecuted — Perry D Parks, a chiropractor of Portsmouth, Ohio was indicted in October by the Grand Jury of Scioto County on a charge of practicing medicine illegally He pleaded not guilty and was released on bond

Sue for Licenses — Two chiropractors, Calvin C Rutledge of Bowling Green and Joseph W Netrefa of Cleveland have filed suits against the State Medical Board to compel the granting of certificates to practice which the board had refused to issue

Academy Election — At the annual meeting of the Columbus Academy of Medicine, December 18 Dr Ernest Scott, Clintonville, was elected president Dr Raymond A Rice, Columbus, vice president, and Dr Ivor G Clark, Columbus, secretary-treasurer

Illegal Practitioner Arrested — "Dr" Roland O McFarren of Massillon, Ohio, was arrested recently on the charge of practicing medicine without a license He is said to prescribe "Dr McFarren's Vegetable Compound" He pleaded not guilty and was released on bond

Divine Healer Arrested — A self-styled "divine healer," Mary A Rose, also known as Delia Deimling is reported to have been arrested at Springfield, Ohio, recently, charged with practicing medicine without a license She pleaded guilty and was released on condition that she leave the state and never return

Cincinnati

Personal — Dr Rufus B Hall, senior gynecologist at the Cincinnati City Hospital has resigned after nearly twenty years' service——Dr Fletcher Langdon fell down stairs December 12, sustaining severe injuries to the shoulder and nose——Dr J Edward Pirrung has been appointed assistant police and fire surgeon

PENNSYLVANIA

Endowment Raised — The campaign for $200,000 for the endowment fund of the Woman's Medical College, Pennsylvania, has just been successfully completed

Gift of Portrait — The Philadelphia County Medical Society is indebted to Richard Y Cooke, president of the Guarantee Trust and Safe Deposit Company of Philadelphia, for a portrait of William Lambdin Knight, M D, eighteenth president of the society

Personal — Dr J Madison Taylor delivered an address before the College of Physicians, Pittsburgh, December 14, on "The Scope of Reconstructive Therapeutics"——Dr Daniel J McCarthy has returned after a visit of inspection to the prison camps in Germany——R A Millikan, professor of physics at the University of Chicago, delivered an address on 'Radiation from Atoms and Electrons," at the Franklin Institute January 4——Dr Arthur S Hagan, Uniontown, who was operated on six weeks ago at the Lakeside Hospital Cleveland has returned home convalescent——Dr George B Kalb, after eighteen years of practice at Erie, has moved to Los Angeles——At the one hundred and fourth annual meeting of the Academy of Natural Sciences, held in Philadelphia December 19, Dr Samuel G Dixon, state commissioner of health was elected president, and Dr Edward J Nolan, librarian

Nurses May Give Anesthetics — W H Keller, first deputy attorney general has given an opinion to Dr John M Baldy, Philadelphia president of the State Bureau of Medical Education and Licensure, that it is not illegal for a nurse who has been trained in the administration of anesthetics to administer such anesthetic as may be prescribed by a physician under and in accordance with his orders and directions Mr Keller says that there is nothing in the law which places the administration of an anesthetic on a different or higher plane than that of any other drug

Examination of Schoolchildren Approved — Dr Samuel G Dixon, state commissioner of health has approved the plan adopted in Pittsburgh to examine all schoolchildren before the opening of school and has advised other school districts to adopt it if possible In Pittsburgh the children come in groups of a dozen or more to the schools to be examined by voluntary physicians and medical inspectors and are given health certificates to show they are free of infantile paralysis, diphtheria, scarlet fever and measles However, no state order for such examination has been sent out

Contagious Diseases — The total number of cases of poliomyelitis in the state from July 1 to Dec 10, 1916, was 2 003, with 494 deaths In July there were 110, August, 714, September, 778, October, 364 and November, 35 The state health commissioner has issued a circular calling attention to the law requiring every school in the state to be fumigated twice a month At Williamsport an epidemic of diphtheria in one of the schools led to an investigation from which the health officer concluded that the bubble fountains were responsible for the spread of the disease In one of the grades the children were so small that they could not drink from the fountains without the lips coming in contact with the cup or pipe In this school use of the bubble fountain was discontinued and individual paper drinking cups provided Eighteen cases of diphtheria had occurred among pupils since the opening of school

UTAH

New Officers — At the annual meeting of the Salt Lake County Medical Society, December 14, the following officers were elected president Dr Robert H Hampton, vice president, Dr George G Richards, secretary, Dr Thomas A Flood (reelected), and treasurer, Dr William L Rich, all of Salt Lake

Infectious Diseases—During the first seventeen days of December there were 191 cases of contagious diseases in Ogden according to the semimonthly report of the health inspector Of the cases, 21 were scarlet fever, 2 diphtheria, 163 measles and 5 chickenpox There were three deaths, all attributed to measles, the epidemic of which was then subsiding In Salt Lake City during the same period it was said that there were about 500 cases of measles

VERMONT

Licenses Revoked—The annual report of the Vermont Board states that the license of Dr John W Merrow has been revoked because of unprofessional conduct and fraudulent representation Since the revocation, it is reported that Merrow has been arrested in New York for illegal transactions in the distribution of narcotics

WASHINGTON

Washington Law Upheld—The supreme court of Washington rendered a decision, December 5, holding that the Medical Practice Act of that state was constitutional This decision was the result of a test case brought by Clyde Boreham, an osteopath, who was alleged to have practiced medicine and surgery without a proper certificate, in that he had removed a patient's tonsils He was licensed to practice osteopathy only, and the court held that he was not entitled to perform the operation on that certificate The lower court assessed a fine of $1 and costs

CANADA

Tuberculosis in Canada—In 1908 there were only 250 beds for the tuberculous available, in 1911 900, today there are 2 000 in the various special hospitals and sanatoria throughout the Dominion

Loss of Life in Asylum Fire—The Asylum for Feeble-Minded Girls at St Ferdinand de Halifax, near Lake William, Megantic County, Quebec was destroyed by fire December 31 In spite of the heroic efforts of the sisters to save the patients, forty-five children died and one of the sisters was also burned to death

Deaths and Births in Ontario in 1915—The total number of births registered in the province of Ontario in the year 1915 was 67,032, as against 66,225 in the previous year The total number of births in the same year was 34,701 males and 32 331 females The illegitimate births numbered 1,472, three more than in 1914 There were 678 twin births and 12 cases of triplets Tuberculosis numbered 2,466 deaths, an increase of 122 over the previous year The deaths from cancer totaled 1 982, an increase of 68 over 1914 The provincial board of health of Ontario is now conducting a campaign of education in respect to cancer and other diseases In infant mortality the deaths under 5 years totaled 8,632, under 1, 6,838

Civil Versus International War—To show what great work lies before the Canadian people in prosecuting a vigorous campaign for the eradication of communicable diseases, the *Health Bulletin* Toronto, compares the deaths in the Canadian Expeditionary Forces to date, with the deaths from typhoid and tuberculosis in Canada in the two years of war The deaths from all causes in the Canadian forces in the war, during two and one-quarter years, have totaled 15 766, while from typhoid and tuberculosis in the same time they have totaled 17 350, or 1,584 more deaths from the two latter diseases than have occurred in war The deaths from the group typhoid, scarlet fever, diphtheria, whooping cough tuberculosis and measles, in the same time, have been 22,560 an excess over war deaths of 6,794 If Canada could prevent this wholesale destruction of human life in peace times repopulation could be effected in a few years

Medical Inspection of Schoolchildren—January 1 the electors of Toronto voted on the question of placing the medical inspection of schoolchildren under the medical officer of health Since its inauguration some six years ago, it has been under the control of the board of education, with a chief medical inspector and several assistants and school nurses Lately, however, it has been found that the work of the school nurses and those of the well-organized department of health was being duplicated, and as there is every evidence of a desire to save on the part of the taxpayer, and as the board of health and the board of education could not arrange terms for amalgamation which amalgamation has been estimated would save at least $35 000 to the city annually, it was decided to submit the proposition to the electors at the municipal elections The medical officer of health Dr Charles J. Hastings, has issued a bulletin, setting forth the work of the department under his charge, in the form of a chain, which showed one link missing namely, that of medical inspection of schoolchildren, and showed a continuous chain of health department activity as adopted in New York Chicago, Philadelphia and other large cities of the United States The results of the election will be announced in a later issue of The Journal

GENERAL

Meningitis on the Border—Army medical officers on the border report that there is no danger of the spread of meningitis among the troops Among the Georgia troops there had been three deaths, and in a Pennsylvania regiment there were two cases, the patients being on the road to recovery No new cases had developed in the eight days previous to the report

Importation of Cassia and Other Spices—The exportation from Hongkong to the United States of cassia for the first nine months of 1916 amounted according to *Commerce Reports*, Dec 28 1916 to $365 520 gold as compared with $67 817 in the same period of 1915 The exports of cassia oil were valued at $88 312, as compared with $37,550 for the nine months of 1915 The exports of spices to the United States were valued at a higher sum for the period named than for any whole previous year

American Congress on Internal Medicine—This organization held its second meeting and first scientific session in New York, December 27 and 28 at the Hotel Astor Dr Reynolds Webb Wilcox in his presidential address, defined the aims and purposes of the organization and the conditions of membership The first scientific session was devoted to a discussion of "The Ductless Glands in Cardiovascular Diseases and Dementia Praecox" and the second scientific session to a symposium on 'Duodenal Ulcer" The following officers were elected president, Dr Reynolds Webb Wilcox New York, vice president, Dr Elias H Bartley, Brooklyn secretary-general, Dr Heinrich Stern, New York, and assistant secretary, Dr Joseph H Byrne, New York, councilors for five years, Dr Jacob Kaufmann New York, Dr Charles G Jennings, Detroit, Dr Judson Daland, Philadelphia, Dr Francis X Dorcum, Philadelphia, Dr Arthur W Fairbanks Brookline, Mass The secretary announced that the organization already had a paid up membership of over 300 and a considerable number of applications for membership

Seaboard Association Meets—The twenty-first annual session of the Seaboard Medical Association was held in Washington, N C December 19 to 22 under the presidency of Dr David T Tayloe, Washington, N C A public health session was held which was well attended and at which addresses were made by Surg Frederick C Smith, U S P H S and Drs J Howell Way Waynesville, Cyrus Thompson, Jacksonville and Charles O Laughinghouse, Greenville, of the state board of health Norfolk Va was selected as the place of meeting for 1917, and the following officers were elected president, Dr Kirkland Ruffin, Norfolk, Va , vice presidents, Drs Joseph L Spruill, Columbia, N C , Robert L Payne, Jr , Norfolk, Va , Ira M Hardy, Kinston, N C , and Rufus L Raiford Sedley, Va , secretary Dr Clarence Porter Jones Newport News, Va , and treasurer, Dr George A Caton Newbern, N C

Baby Week for 1917—Stimulated by the success of Baby Week last year, the Children s Bureau U S Department of Labor, is making plans for a bigger and better Baby Week for 1917 The bureau and the General Federation of Women s Clubs have agreed on the week beginning May 1 as the time most generally suited for the event, and urge that this week be adopted wherever local conditions permit An effort will be made to have the welfare work incident to the week extended so as to cover all children still at home with their mothers and not limit the work to the period of infancy only Stress is laid on the fact that well-cared-for and healthy mothers are necessary for the health and happiness of babies and the importance of protecting the mother particularly during pregnancy and the lying-in period will be urged Caution is given that in communities where infantile paralysis has been epidemic, all features should be omitted that might bring susceptible children together but attention is called to the fact that Baby Week may well be so planned as to afford an excellent opportunity for giving information as to the proper physical training of children with paralyzed muscles Persons interested in the planning and management of a Baby

Week can obtain without cost a bulletin on the subject, by applying to the Children's Bureau Washington, D C

Bequests and Donations—The following bequests and donations have recently been announced

Goshen (N Y) Emergency Hospital $10 000 by the will of Harry W Van Cortland

St Christopher s Hospital for Babies Brooklyn N Y, $87,103 by the will of Harrison Pownal Wallis

Sanatorium for members of the International Ladies Garment Workers Union suffering with tuberculosis property valued at $75 000 donated by Miss Martha Hentschel Kingston N Y

Pennsylvania Hospital Philadelphia $5 000 Society for Organized Charity $5 000 Bryn Mawr Hospital Philadelphia Hospital for Women Frederick Douglass Hospital Lying In Hospital Philadelphia Children s Aid Society Friends Insane Hospital and Oncologic Hospital each $2 000 by the will of Joshua L Bailey

Germantown (Pa) Dispensary and Hospital, $100,000 by the will of Mrs Mary Warden Harkness

Long Island College Hospital Brooklyn N Y bonds of the market value of $50 000, a bequest from Dr John A McCorkle

Public Nurse Association Peoria Ill a donation of $1 000 by Trustees of the Proctor Endowment

United Hebrew Charities Montefiore Home German Hospital and Mount Sinai Hospital New York each $1 445 by the will of William Josephy

The Association for Improving the Condition of the Poor St Luke s and the Presbyterian Hospital New York each $100 000 by the will of Harris C Fahnestock A legacy of $100 000 was also paid to the Post Graduate Hospital by the decedent just before his death

Polyclinic Hospital New York $47 767 the Association for Improving the Condition of the Poor the New York Skin and Cancer Hospital and the Laboratory for Surgical Research of New York University each $25 883 by the will of Mrs M P Draper

Jewish Foster Home Philadelphia United Hebrew Charities Jewish Hospital and Philadelphia Jewish Sanatorium for Consumptives each $500 by the will of Mrs Bertha Rosshan

Philadelphia Home for Incurables Home for Consumptives Samaritan Hospital Presbyterian Hospital and Children s Homeopathic Hospital each $5 000 by the will of John T Martin, Philadelphia, the bequest payable after the death of his widow

FOREIGN

Epidemics in Sonora—At Uics in the state of Sonora, 160 miles south of the Mexican border it was reported December 18, that smallpox in virulent form and a mysterious fever believed to be typhus had caused more than 500 deaths in the previous four weeks An epidemic was also said to exist in the Alamosa district Quarantine was said to be in force in the affected districts

Import Prohibition on Alcohol—By a decree of Dec 22, 1916, according to *Commerce Reports*, Dec 28, 1916, the French government has prohibited the importation of alcohol and certain alcoholic beverages of foreign origin into France and Algiers The prohibition is not applicable to shipments for government account for storage and reexport, or for chemical and pharmaceutical purposes

Conservation of Mineral Springs—By a decree issued by the president of Peru the exploitation of all mineral springs in that country will be under the direction of the public health department (*Commerce Reports* Dec 22, 1916) The department will disseminate information on the curative properties of the native mineral waters and prevent the misuse of the springs and will take charge of the baths and depots where the waters are taken

Plague in India—Rev Henry Fairbanks, Ahmednager, India reports that bubonic plague has been increasing for three months or more and is more severe than has been noticed for several years Cats and rats were reported to be dying in many parts of the city and the people fled panic stricken and died elsewhere spreading the disease Dr Ruth P Hume has started a campaign of inoculation, and with Dr Lester H Beals of Satara, has already inoculated 14 000 persons

Sanitation in Shanghai—The city of Shanghai is only partially supplied with modern methods of sewage disposal Only the French section it is said, is provided with septic vaults and other improvements The other portions of the city still cling to the old methods on account of the commercial value of waste products According to *Commerce Reports* Dec 27, 1916, the matter of modernizing the disposal of sewage for the whole city is under discussion, due largely to the increased cost of cleaning vaults, which is said to be almost prohibitive

Chemical Industry in Russia—The chemical industry in Russia has received great impetus from the war and according to *Commerce Reports* Dec 23, 1916, a number of works have already been erected and many others are projected Among them is a formaldehyd factory at Vetluga, and a technical laboratory for the production of lanolin, naphthalene, etc, at Rostov A large company has been formed at Moscow for the production of coke-benzol products and at Tomsk a chemical factory is projected for the making of medical chemicals Several new works for making sulphuric acid have been erected in the Volga region, in the Donets basin, in the Caucasus and in the Urals Mirrors, lenses and other optical instruments, thermometer tubing and chemical glass, formerly imported, are now being made There is a large demand for microscopes and other scientific apparatus, as well as for articles for medical and surgical use

LONDON LETTER

London, Dec 11, 1916

The State Treatment of Venereal Diseases

This subject has already been described in The Journal Progress is being made in most parts of the country with the schemes for providing additional facilities for diagnosis and treatment, in accordance with the recommendations of the royal commission, which have been adopted by the government The Portsmouth scheme has already been described For East Sussex it is intended to provide further clinics An early start will probably be made with the new work at Addenbrooke's Hospital at Cambridge The Norfolk and Norwich Hospital at Norwich is also early in the field, and arrangements for the establishment of a treatment center are being made with the local county councils In the West Riding of Yorkshire it is proposed to establish in the first instance treatment centers at Sheffield, Leeds and Bradford, and in due course to extend the scheme so as to include some of the smaller hospitals in the county Negotiations between the municipalities of Birmingham, Liverpool and Manchester, and the large hospitals in those towns are proceeding In the case of some of the small rural counties it has been found impracticable to arrange for suitable treatment at any institution in the county, arrangements will have to be made with the nearest available hospital outside the county Thus in the case of Westmorland the county council intends to use the Manchester Royal Infirmary, and patients in need of special treatment will have to undertake the journey to that city

The London County Council Public Health Committee has prepared a scheme for the metropolitan area It is to come into operation January 1, and will extend to the areas bordering on the county Associated with it are the county councils of Buckingham, Essex, Hertford Middlesex, Surrey and Kent, and the borough councils of Croydon, East Ham and West Ham Arrangements for diagnosis and treatment and the provision of laboratory facilities have been made with the principal London hospitals The services will include the appointment of a committee of the hospital staff to draft a scheme for carrying out the special work at the hospital relating to the diagnosis and treatment of venereal disease, and to organize and superintend the arrangements within the hospitals, the appointment of a competent staff, the provision of beds for the patients, the treatment of outpatients at evening clinics at other suitable times, the supply by the hospital of salvarsan or its substitutes on an approved list, the supply to physicians of apparatus for taking specimens, and the furnishing of them with reports, the examination of specimens sent by physicians, the supply of statistical information of work done, the provision of free instruction for physicians and students, opportunities for physicians to act as clinical assistants at approved rates of remuneration, the employment of women physicians in clinics for women and the issue of printed instructions for the guidance of patients and physicians The hospital will receive payments in respect of (*a*) the work of the treatment center, including the supply of salvarsan or approved substitutes and any pathologic examinations of specimens, and (*b*) the pathologic examination of specimens sent to the hospitals by physicians in the areas of the various authorities These payments will amount in 1917 to $167 000, of which London s share will be $97,750 The cost of the supply of drugs to London physicians during the first year is estimated not to exceed $250,000 To this must be added the cost of supplying salvarsan or its approved substitutes to poor law infirmaries and district and poor law medical officers, amounting to about $37,500, making a total of $137,500 It appears to the committee that any scheme for dealing with the disease would be incomplete unless supplemented by instructional lectures and the publication of information, and it has therefore included a sum for this purpose in the estimate of expediture

At the London Hospital the scheme will be in full operation, January 1 In consideration of the payment of $15,C00 a year by the London County Council, the hospital will provide treatment for all patients with venereal diseases coming from the areas of the participating authorities The arrangements will consist of two parts 1 A department for the treatment of genito-urinary diseases, the hospital will provide four sessions a week, two for men and two for women, the sessions for men to remain open until 7 p m The hospital will appoint two clinical assistants, one senior and one junior the latter to be increased if necessary by the appointment as far as possible of local general physicians 2 A department for the treatment of syphilis, in which, in addition to the ordinary outpatient treatment, salvarsan or approved substitutes will be administered The hospital will appoint an additional assistant The hospital will allot fifteen beds for the purpose of treating syphilis, and a certain number of beds for genito-urinary diseases To insure secrecy the ward system will not be adopted each patient being provided with a bed in a room occupied solely by him The hospital will make arrangements for the examination of specimens sent by physicians in the participating areas whose patients do not attend the hospital

The Work of the Research Committee

The second annual report of the Medical Research Committee appointed under the national health insurance scheme has been issued A great deal of useful work has been accomplished The needs of a nation at war have been kept in view The work in connection with the war began with the help given to the army by the statistical department in compiling army medical statistics A card index has been made for all military hospitals in the United Kingdom now numbering over 2 000, and a similar index for stations and hospitals abroad is in progress of construction This work, when completed, will serve a national purpose of the highest importance, wholly additional to its immediate military and scientific value For many years after the conclusion of peace claims for pensions or allowance must be expected to be advanced by men not invalided from the forces during service, or by their kinsmen or relatives These claims will be based on disabilities alleged to be due to wounds or sickness on active service, and the only means of tracing the accuracy of statements made in support of these future claims will be the card index now being compiled from the hospital records It is understood that huge financial loss has been sustained by the American government in consequence of the incompleteness of contemporary records during the stages of the Civil War

Treatment of Wounds

Striking results have attended the study of wound infections and their treatment in the field and hospital The idea that the dirty and often extensive wounds of warfare can be cleansed as a routine surgical procedure by the direct application of a strong antiseptic has been abandoned Treatment of wounds is now directed to the facilitation of the physiologic processes of the body, on which Wright laid stress, by surgical methods for securing drainage and by irrigation methods of maintaining it, and of combating the invading organisms Surgical testimony is still divided on the respective values of Wright s treatment by salt solutions alone without antiseptics, on the one hand, and, on the other, treatment by irrigation with Dakin's hypochlorite solutions though both methods now are widely applied The use of salt or of hypochlorite solutions both of which are very cheap as compared to other antiseptics, has led to a great saving in hospital expenditure Much work has been done on the properties of many old and new poisonous gases with a view to improving the means of their ready detection and identification, the methods of protection against them, and of antidotal and other modes of treatment in cases of poisoning Reference is made to the success of the preventive measures adopted in Egypt against the infection of the troops with bilharziasis From 80 to 90 per cent of the natives in the Nile delta are known to be affected by this disease for which no cure is known when the worm is once established in the blood of its human host Some idea of the immensity of the national interest in this disease and in its adequate control at the present time in Egypt, may be gained from the statement that of the men infected with bilharziasis during the South African War, 359 were still receiving "conditional pensions" in 1911 at a cost to the state of about $32 000 per annum exclusive of those already permanently pensioned

Clinical Facilities for Women

The subcommittee of the Academic Council on Medical Education of Women in the University of London has just issued a report On the further provision of clinical facilities for women students in London, it is stated that no anxiety need be felt about teaching men and women together, though the deans of the various schools have supported the idea that the men students would object to the presence of women students The reasons generally given for this are (*a*) Women are keener in their work and take the front places at demonstrations and obtain an unfair share of clinical opportunities, (*b*) women are unable to contribute to the athletic life of the school The committee is of opinion that no valid objection can be maintained against the system of coeducation for men and women medical students and that this is the only system by which the general policy of the University of London can be effectively carried out The subcommittee considers that the facilities for the medical education of women would not be adequate in any hospital or medical school unless resident medical and surgical appointments are open to men and women on equal terms and it hopes that these facilities will be provided in some of the schools of the university at no distant date In October, 1916, 127 students entered the London School of Medicine for Women, twenty women entered at Charing Cross Hospital Medical School and King's College, making a total of 157 women students in London Of these, 115 are in their first year

The Professorial Board of University College, London has reported on the foregoing report, and while agreeing with it in many respects differs in-others For example, it is stated that 'if women were admitted to only a few schools, there is reason to believe that those schools would lose men students and would become mainly schools for women" The board therefore, which had been urged to open the anatomy department at University College to women recommends 'That the question of admitting women to the department of anatomy be deferred until adequate provision of clinical facilities for women students in London has been made and until it is possible to provide suitable accommodation for them"

PARIS LETTER

Paris, Dec 7, 1916

The War

PROTECTION OF MATERNITY DURING THE SECOND YEAR OF WAR

Last year Dr Pinard formerly professor of clinical obstetrics at the Faculte de medecine de Paris, communicated to the Academie de medecine statistics showing that protection of maternity and of the new-born in Paris had been so well effected during the period 1914-1915 that the mortality under these two heads was actually lower than in the preceding periods, which is the reverse of what previous war time experience would lead us to expect These happy results were due chiefly to the particular attention paid to the mothers and children by the Assistance publique (The Journal March 20, 1915, p 1010) Recently Pinard reported to the Academie results in Paris for the second year of war Of 26 179 births registered in Paris 95 per cent were attended by agents of the Assistance publique While the measures of protection have remained the same during the past year the results have been less satisfactory The number of stillbirths fell from 7 69 to 6 63 per cent., the number of children nursed by wetnurses from 31 to 13 55 per cent , mortality of mothers from 0 64 to 0 46 per cent and desertion of infants from 4 98 to 2 88 per cent In the second period these figures rose again, being, respectively for 1916, 7 67, 22 0 48 and 5 21 per cent On the other hand, infant mortality has remained practically stationary for the first year of life, but has increased for the second year The cause of this increase is found in infectious diseases particularly measles and whooping cough The increase in the number of abandoned and premature children, the diminution in the average weight of the new-born and the decrease in the number of meals served by the maternity canteens to nursing mothers have an economic cause which Pinard points out as the presence of pregnant and nursing women in ammunition factories These women are unaware of the danger to themselves and of the risks to which they expose their children Pinard therefore demands that employment at these factories should be forbidden every pregnant woman, every woman nursing a child and every woman who has been confined within six months

THE URGENT SURGERY OF LUNG WOUNDS

Dr Pierre Duval of the Faculte de medecine de Paris and surgeon of the hospitals, recently reported to the Societe de chirurgie de Paris fourteen cases of urgent operation for wounds of the lung All of these operations were performed to arrest a pulmonary hemorrhage threatening the life of the patient, or for the relief of serious asphyxia They were, therefore, operations of extreme urgency performed on patients in imminent danger These observations show the value of this intervention, for of the fourteen patients, ten were cured The technic employed was that devised by Duval resection of a single rib wide opening of the pleura, suturing of the wounds by deep hemostatic sutures, drying of the pleura and suture of the thoracic wall In such cases the projectile is removed only if easily found

MEDICAL ASSISTANCE TO DISCHARGED SOLDIERS

The minister of the interior has appointed a commission to study means of securing medical and pharmaceutical assistance or hospital accommodation for soldiers discharged for wounds or illness contracted or aggravated while with the colors

THE AMERICAN MEDICAL DETACHMENT WITH THE ARMY

A number of Americans who have devoted themselves to the service of our wounded have collected their souvenirs in a volume which has just been published under the name of Friends of France The preface of this is written by Mr A Piatt Andrew, inspector general of the American medical sections

ALTERNATING USE OF ANTISEPTICS

Dr Charles Richet professor of physiology of the Faculte de medecine de Paris recommends that surgeons alternate one antiseptic with another in the treatment of infected wounds in order to avoid the possibility of germs becoming habituated to poisons In a communication to the Academie des sciences, Dr Richet divides antiseptics into four groups (1) oxidizing agents (hypochlorites hypobromites, iodin chlorin, hydrogen peroxid, ozone, potassium permanganate, etc), (2) compounds of heavy metals (salts of mercury, silver, copper zinc, etc), (3) substances belonging to the aromatic series (phenols, salicylates, thymol, naphthol, creosote, etc), and (4) miscellaneous products (formic aldehyd chloroform, chloral, essential oils fluorids, boric acid, etc) One may thus employ an antiseptic of the first group on the first day one of the second group on the second day, and so on In these conditions the microbes do not have an opportunity to develop immunity to the antiseptic, and the results obtained are much better

EAR DISEASES AND THE WAR

Affections of the ear are frequent in the army, and take up much of the time of military surgeons Dr J Moliniè has made a report on this subject to the Reunion medicale de la I-ere armee He groups the cases in three categories (1) diseases contracted while with the army, (2) lesions caused by engines of war,' and (3) exacerbations or aggravations of chronic affections Ear diseases contracted in the army constitute 21 per cent of the whole number The most common of these is acute otitis media following affections of the upper respiratory passages fevers and infectious diseases From 7 to 8 per cent of these cases are accompanied by mastoiditis This condition is almost invariably cured in from three to six weeks, and the patient is able to resume his service The lesions caused by 'war engines" constitute about 28 per cent The external ear is occasionally injured, but it is usually the middle ear which suffers Unilateral or bilateral perforation of the tympanum is frequent The ossicles are occasionally dislocated Traumatic perforation of the tympanum is characterized by the presence of a narrow hemorrhagic border The treatment is plugging of the external meatus with antiseptic cotton The loss of hearing is slight, and the patient is soon fit to resume his service Deafness from shock is less frequent than that due to traumatic perforation As a rule, it amounts to little more than a kind of auditory 'dazzling' which disappears completely with time True and persistent lesions of the labyrinth are an exception The most intractable cases of shock deafness are of psychic origin and are not infrequently simulated The auditory-palpebral reflex is of value in the differential diagnosis of these different conditions These cases of shock deafness are becoming more and more numerous with the increasing use of heavy artillery Their numbers are, in a certain sense, an index of the fluctuations in the struggle It will be possible to reduce these numbers by protecting the ear of the combatant, either by means of a flapped cap worn under the helmet, or by a metallic ear protector attached to the helmet and capable of being lowered or raised at will Of the ear diseases among soldiers calling for treatment, 51 per cent are chronic affections either aggravated or exacerbated This group is practically evenly divided between chronic suppurative otitis media, and chronic deafness The prevalence of the former has been the occasion of a new regulation to the effect that intermittent suppurations must be treated at the front if the lesions are limited to the middle ear But these new regulations cannot become effectual, unless the patient can be seen by a specialist who will decide whether his case falls within their scope Chronic deafness is often attributed by the patient to the noise of the cannon There is practically never any improvement from treatment in these cases, and the specialist's task is limited to formulating an opinion as to the military fitness of the patient In forming judgment on this, it is not sufficient to take into consideration an estimate of the acuity of the hearing as tested in the usual way For this special purpose it is necessary to allow for certain compensations, natural or artificial, of slight deafness The extent of compensation can be judged only by a careful observation of the patient in the ordinary surroundings of his life Further, the specialist has to bear in mind that there are occupations in the army for which his patient may be suitable in other respects and which do not require acute hearing

Turning now to war victims suffering from total bilateral deafness, the method of reeducation by lip reading appears to give excellent results This system is being generalized in all centers in the interior of the country With regard to complete deafness, the important problem presents itself of differentiating between pathologic conditions and malingering It is now well ascertained that in addition to complete deafness dependent on organic lesions, there are other genuine cases in which no morphologic change can be demonstrated Differential diagnosis acquires especial importance because of the difference in prognosis in the two cases For this reason it is necessary to employ the most precise scientific methods to eliminate as far as possible every source of error, and, in particular, that which may be due to insincerity of the patient In this connection it appears likely that investigation of the ocular and vasomotor reflexes under a purely auditory stimulus should offer the surest guarantees The number of patients suffering from ear discharges is considerable, and constitutes a heavy burden on the specialists It is the practice at present to retain patients suffering from chronic otorrhea with the army This is in correlation with the fact that for the most part ear trouble has never interfered with work in civil life It is, of course, necessary to give these patients treatment for a few days Such a treatment properly applied occasionally leads to complete cure In the absence of complications calling for mastoid operation, ear discharge is not considered incompatible with service in the army

---

Marriages

Victor Luman Rocho, M D, Woodburn, Ore, to Miss Ruby Esther Francis of Oregon City, Ore, December 14

Theodore Livingston Chase, M D, to Agnes Barr, M D, both of Philadelphia, in New York, December 6

Kent Edward Darrow, M D, Fargo, N D, to Miss Cora Belle Hodgson of Gardner, N D, December 2

Blaine Augustus Young, M D, Merriman, Neb, to Miss Edith C Barnes of Cody, Neb, December 24

James Alphonso Taylor, M D, to Miss Jessie Craven both of Montpelier, Ind, December 22

Charles Edward Scharf, M D, to Miss Grace Elizabeth Mullin, both of Chicago, November 30

Edwin Everett Jack, M D, Boston, to Miss Mary J Denny of Brookline, Mass, December 11

William John Gatti, M D, to Miss Rose Wery, both of Punxsutawney, Pa, November 15

Stephen Hurt Watts, M D, University, Va, to Miss Sarah Tilt of Atlanta, Ga, December 21

Norman Dixon Curry, M D, to Miss Neal Jelleneoux, both of Chicago, in October

John McCoy, M D, to Miss Florence A Riley, both of New York, December 8

Deaths

Claude Lamont Wheeler, M D, New York, McGill University, Montreal, 1889, aged 52, died at his home in Brooklyn, December 30, from pneumonia Dr Wheeler was for many years assistant editor of the *New York Medical Journal* under the late Dr Frank P Foster, and succeeded the latter in the editorship of the journal

Holliday H Hayden, M D, Baltimore, College of Physicians and Surgeons, Baltimore, 1892, aged 47, a Fellow of the American Medical Association, demonstrator of anatomy and clinical medicine in his alma mater, later associate professor of applied anatomy in the University of Maryland, vaccine physician of Baltimore, died at his home, December 20

William Francis Skinner, M D, Chambersburg, Pa , Jefferson Medical College, 1890, aged 48, a Fellow of the American Medical Association, president of the Cumberland Valley Medical Association in 1913, a member of the staff of the Chambersburg Hospital, coroner of Franklin County, died at his home, December 18

Richard M Thomas, M D, Greensburg, Ind , Medical College of Ohio, Cincinnati, 1883, aged 58, a member of the Indiana State Medical Association, local surgeon for the Big Four System, died in the Good Samaritan Hospital, Cincinnati, December 17, after a surgical operation

William F Smith, M D, Glenn Springs, S C , University of Pennsylvania, Philadelphia, 1861, aged 82, for more than a half century a practitioner of Spartanburg County, S C , surgeon in the Confederate service during the Civil War, died at his home, December 3

J Thomas Nunnally, M D, Griffin, Ga , Memphis Hospital Medical College, Memphis, Tenn , 1894, aged 45, formerly a Fellow of the American Medical Association, a member of the Tennessee State Medical Association, died at his home, December 15, from nephritis

T M Cherry, M D, Norton, Va , College of Physicians and Surgeons, Baltimore, 1891, aged 54, a Fellow of the American Medical Association, a well known practitioner of southwest Virginia, died at his home, December 11, from cerebral hemorrhage

Carter E Damrell, M D, Tulsa, Okla , Central Medical College, St Joseph, Mo, 1898, aged 42, for eight years health officer of Enid and Garfield County, Okla , died at the home of his father-in-law in Enid, December 17, from organic heart disease

George W Bailey, M D, Philadelphia, University of Pennsylvania, 1868, aged 76, who gave up his practice twenty-two years ago to devote his time to Sunday school work, died in a sanatorium at Battle Creek, Mich , December 19, from disease of the kidney

Emory Oliver Onion, M D, Summum, Ill , Keokuk (Iowa) Medical College, 1906, aged 38, a Fellow of the American Medical Association, died, December 16, in the Macomb (Ill) Hospital, where he had been under treatment for tuberculosis

James Lawrence Sullivan, M D, Bridgeport, Conn , College of Physicians and Surgeons, Baltimore, 1901, aged 42, a member of the Connecticut State Medical Society, died in St Vincent's Hospital, Bridgeport, August 12, from Hodgkin's disease

Lee B Harvey, M D, Colville, Wash , Marion-Sims College of Medicine, St Louis 1900, aged 48, a member of the Washington State Medical Association, mayor of Colville from 1900 to 1909, died at his home, December 16, from acute nephritis

Milton Oscar Stemmler, M D, Myrtle Point, Ore , Marion-Sims College of Medicine St Louis 1900, aged 45, formerly a member of the Oregon State Medical Association, died in Mercy Hospital, North Bend, Ore , December 14 from typhoid fever

Frederick Frelinghuysen Coleman, M D, Asbury Park, N J , New York University, New York, 1893, aged 52, a graduate in pharmacy, died at a private sanatorium in Stamford, Conn , November 27, from disease of the brain

Charles Henry Linley, M D, Atchison, Kan , Miami Medical College, Cincinnati, 1877, formerly a member of the Kansas Medical Society, a resident of Atchison for half a century, died suddenly in that city, December 20

Howard Edwin Hiestand, M D, Kenton Ohio, Medical College of Ohio, Cincinnati, 1884, aged 58, a member of the Ohio State Medical Association, died in Grant Hospital, Columbus, December 15, from myocarditis

Richard Biddle Faulkner, M D, Pittsburgh, College of Physicians and Surgeons in the City of New York, 1875, aged 63, formerly a Fellow of the American Medical Association, died at his home, December 20

William John Coates, M D, New York, New York University, New York, 1882, aged 59, dean of the College of Veterinary Surgery of New York University, died at his home, December 19, from diabetes

Samuel L Cochran, M D, Louisville, Ky , Louisville (Ky) Medical College, 1893, aged 61, formerly professor of anatomy and physiology in his alma mater, died at his home, December 18 from pneumonia

James Joseph Walsh, M D, Olyphant, Pa , Jefferson Medical College, 1911, aged 29, a member of the Medical Society of the State of Pennsylvania, died at his home in Scranton, recently, from diphtheria

James Dorland, M D, Dorland, Ont , McGill University, Montreal, 1875, aged 64, formerly a practitioner of Milwaukee, Wis , and Chicago, died at his home, December 10, from cerebral hemorrhage

David C Knott, M D, Plymouth, Ind , Eclectic Medical Institute, Cincinnati, 1882, aged 59, a Fellow of the American Medical Association, died at his home, November 8, from angina pectoris

James E Lay, M D, Hallettsville, Texas, Tulane University, New Orleans 1868, aged 73, a Fellow of the American Medical Association, a Confederate veteran, died at his home, December 13

William David Hollmers, M D, Chicago College of Physicians and Surgeons, Chicago, 1915, an intern in Cook County Hospital, Chicago, died in that institution, December 23, from typhoid fever

Josaphat A Gaucher, M D, Putnam, Conn , Baltimore Medical College, 1912, aged 26, a Fellow of the American Medical Association, died at his home, December 17, from lobar pneumonia

Wesley R Churchill, M D, Reedsburg, Wis , Hahnemann Medical College, Chicago, 1874, aged 71, a specialist on diseases of children, died at his home, December 7, from pneumonia

Warren Bateman Brown, M D, Richmond, Calif , Starling Medical College, Columbus, Ohio, 1888, aged 54, founder of the first newspaper in Richmond, died at his home, December 10

John Beach Knapp, M D, New York, College of Physicians and Surgeons in the City of New York, 1875, died in St Luke's Hospital, December 18, from postoperative pneumonia

Elery Channing Webster, M D, Marion, Ind , Eclectic Medical Institute, Cincinnati, 1868, aged 72, died at his home December 17, from cerebral hemorrhage

John Leonidas Murray, M D, Lexington, Tenn , Vanderbilt University, Nashville, Tenn , 1874, aged 74, a veteran of the Civil War, died at his home, December 8

Frederick Haskins, M D, Neosho, Mo , Ensworth Medical College, St Joseph, Mo, 1903, aged 54, died in St Joseph, Mo , December 17, from pneumonia

Francis Mason Hayes, M D, Buffalo, New York University, New York, 1887, aged 63, died in Lewiston, N Y, December 10, from pneumonia

Charles E Bennett, M D, Cortland, N Y , Syracuse, N Y, University, 1880, aged 58, died in the Cortland Hospital, November 30, from septicemia

W L Hayne, M D, Mallorysville, Ga , Georgia College of Eclectic Medicine and Surgery, Atlanta, 1889, aged 63, died at his home, December 4

Joseph D Boggs, M D, Norborne, Mo , Kansas City, Mo, Medical College, 1886, aged 82, died at his home, December 3, from nephritis

Frank W Le Fevre, M D, Portland, Ore , Cleveland University of Medicine and Surgery, 1885, aged 59, died at his home, December 2

Justin D Root, M D, Brandon, Wis , Hahnemann Medical College, Chicago, 1884, aged 58, died at his home, November 21

James W Grisard, M D, Winchester, Tenn , University of Nashville, Tenn , 1870, aged 68, died at his home, December 7

D Tonjes Krudop, M D, Los Angeles, Hahnemann Medical College, Chicago, 1888, died recently at his home

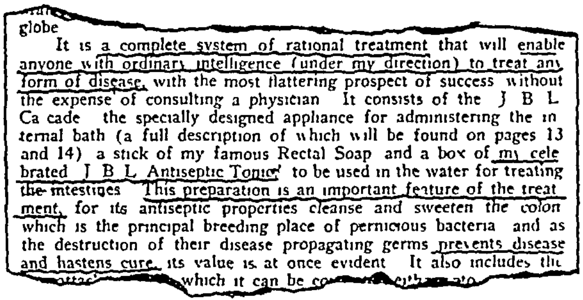
The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

THE J B L CASCADE TREATMENT

The Commercial Possibilities in Rectal Enemas

"The J B L Cascade Treatment" is exploited by one Charles A Tyrrell of New York City It consists in the self-administration of rectal enemas—containing a "patent medicine" sold by Tyrrell—by means of a rectal syringe known as the J B L ('Joy-Beauty-Life') Cascade



globe

It is a complete system of rational treatment that will enable anyone with ordinary intelligence (under my direction) to treat any form of disease, with the most flattering prospect of success without the expense of consulting a physician It consists of the J B L Cascade the specially designed appliance for administering the internal bath (a full description of which will be found on pages 13 and 14) a stick of my famous Rectal Soap and a box of my celebrated J B L Antiseptic Tonic' to be used in the water for treating the intestines This preparation is an important feature of the treatment, for its antiseptic properties cleanse and sweeten the colon which is the principal breeding place of pernicious bacteria and as the destruction of their disease propagating germs prevents disease and hastens cure, its value is at once evident It also includes the which it can be

Photographic reproduction (reduced) of a portion of a page of the booklet sent out by Tyrrell to those who answer his advertisements Imagine a person of ordinary intelligence attempting to treat diphtheria smallpox cancer consumption, Bright s disease etc (any form of disease') with Tyrrell s complete system consisting of a rectal syringe a stick of soap and a teaspoonful of salt and borax in water'

Before discussing the J B L Cascade treatment, it is well to give the reader some facts which, while incidental have a bearing on the subject and will aid in giving a truer perspective of the business under discussion Tyrrell according to our records, was born in 1843 He received a diploma from the Eclectic Medical College New York, in 1900—when he was 57 years old! In addition to the *J B L Cascade treatment*, Tyrrell was president of the concern that exploited the "Ideal Sight Restorer,' sold as a cure for most eye ills This has been advertised under such claims as cures not only the refractive errors of the eye—nearsight farsight oldsight and astigmatism—but also such dreaded diseases as cataract, glaucoma, cross-eye and paralytic blindness" The Ideal Sight Restorer was a piece of tubing with a rubber bulb attached for the purpose of producing a partial vacuum over the eyeballs The disasters that might result from the indiscriminate use of an appliance of this sort in certain diseased conditions of the eye are more obvious to physicians than to the public In advertising this "eye cure" the concern sent out what was claimed to be "an unprejudiced journalistic opinion" from the *United States Health Reports* This publication, which was presumably named so as to mislead the public into believing it was a government bulletin was, to quote from a government report, a fraudulent advertising concern which wrote editorial endorsements for any disreputable institution for a cash consideration" In addition to this sort of testimony for the 'Ideal Sight Restorer," there were also reports from professional testimonial writers

Tyrrell has also appeared in the role of publisher and "editor-in-chief' of a quasi-medical magazine *Health*, issued from the same address as the 'Ideal Sight Restorer" and the "J B L Cascade" He had for associate editor" C S Carr, the quack, who for years was connected with the Peruna concern, and who also exploited a mail-order medical concern of his own The advertising pages of *Health* in addition to giving large space to the "Ideal Sight Restorer," the "J B L Cascade treatment" and Carr's mail-order concern reeked with frauds Brinkler, the "Food Expert,' the make-you-tall "Cartilage Co," the Actina eye-and-ear-cure, the Okola eye-cure the O ydonor swindle and the notorious New York Institute of Science—all of which have been officially stamped as frauds by the United States authorities and denied the use of the United States mails—found haven in the pages of *Health* These facts are given that our readers may get some conception of Tyrrell s business ethics and also for the information of those publishers who have opened the advertising pages of their magazines to the Tyrrell "treatment"

THE "J B L CASCADE'

Tyrrell claims to be the inventor of the J B L Cascade The public is asked to believe that he, "after several years of patient experimenting succeeded in perfecting the appliance that bears his name" Elsewhere Tyrrell declares "I have invented an apparatus the J B L Cascade" What are the facts? According to the United States patent records one Henry M Guild invented the device which was patented in 1903 Guild also invented and obtained an additional patent on a modified form of the device in 1904 Both of these patents were assigned to the Tyrrell concern the first by Guild himself and the second by Guild s executor So much for Tyrrell s claim that he is an inventor!

The J B L Cascade consists essentially of a rubber bag shaped like a typical rubber hot-water bottle A hard rubber injection point is fastened on one of the flat sides To operate the device the rubber bag is filled with the 'J B L Antiseptic Tonic" solution—of which more later—the point is then inserted in the anus and the weight of the body on the bag forces the liquid into the rectum In its essentials the device is virtually the same as one that was patented in Canada in 1892 and in the United States in 1894 by one Joseph Lalonde, a British subject who lived in Winnipeg

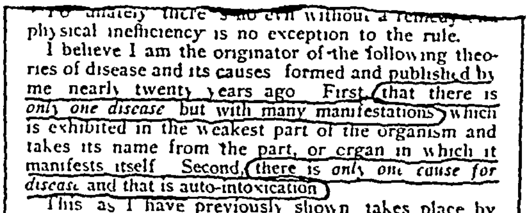
TYRRELL'S KEY-NOTE THEORY

Tyrrell claims to have originated a theory of "disease and its causes" Whether the "theory" was devised as a convenient accessory to his exploitation of the "Cascade" and the "patent medicine' that goes with it, or whether it is merely an indication of stupendous ignorance makes little difference, it is bizarre and fantastic to the point of silliness Here it is

> There is ONLY ONE DISEASE but with many manifestations
> There is ONLY ONE CAUSE FOR DISEASE and that is auto intoxication '

But Tyrrell s theory is no more preposterous than the claims *he has made for his J B L Cascade treatment For instance*

> It enables any one with ordinary intelligence (under my direction) to treat successfully any form of disease that is curable '



physical inefficiency is no exception to the rule.

I believe I am the originator of the following theories of disease and its causes formed and published by me nearly twenty years ago First, that there is *only one disease* but with many manifestations which is exhibited in the weakest part of the organism and takes its name from the part, or organ in which it manifests itself Second, there is *only one cause for disease* and that is auto-intoxication

This as I have previously shown takes place by absorption through the walls of the intestinal canal disregard of natural law For

Photographic reproduction (reduced) of part of a page of one of Tyrrell s booklets Here he gives his theory of disease and its causes

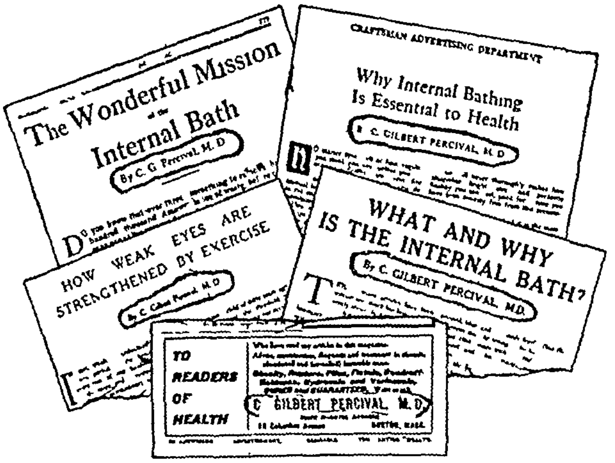
> No matter of how long standing your trouble may be if there is a possibility of cure, this treatment will effect it
> *It is the greatest preservative of health ever known'*
> a system of treatment that will both cure and prevent disease
> My system of treatment should be used by every one whether in sickness or health

These are but a few of the claims that Tyrrell has made at various times for his "treatment '

THE INFERENTIAL UNTRUTH

The Propaganda Department has received scores of inquiries regarding the J B L Cascade treatment Some of these have come from publishers who make some attempt to censor their advertising pages The various absurd claims made by Tyrrell have been pointed out to these publishers Coincidently with these criticsms the Tyrrell advertising has become not more honest but more cautious To illustrate some of the minor modifications in which the direct has given way to the inferential falsehood, we quote in parallels, italicizing to make the comparison clear

OLDER CLAIMS	NEWER CLAIM
I have *cured* thousands "	'I have *benefited* thousands "
my method of *curing* and preventing disease "	' my method of *treating* and preventing disease "
I cleanse the system thereby removing the cause of *all* disease "	I cleanse the system thereby removing the cause, in my opinion, of *much* disease '
Typhoid fever and Appendicitis *are* positively *cured* by the J B L Cascade Treatment '	Typhoid fever and Appendicitis *may* positively be *relieved* by the J B L Cascade Treatment '



The Wonderful Mission of the Internal Bath

Why Internal Bathing Is Essential to Health
C. Gilbert Percival, M. D.

How Weak Eyes Are Strengthened by Exercise
By C. Gilbert Percival, M. D.

What and Why Is the Internal Bath?
By C. Gilbert Percival, M. D.

To Readers of Health
C. Gilbert Percival, M. D.

Greatly reduced photographic reproductions of part of four full page advertisements of Tyrrell s J B L Cascade and Ideal Sight Restorer' These consist of dissertations by one C Gilbert Percival, M D' Percival was one of the associate editors of *Health* a pseudo medical sheet published by Tyrrell We also reproduce one of Percival's own advertisements in which he guaranteed a cure of obesity, rupture piles hydrocele etc Percival has given testimonials also for Absorbine Jr " Somnos" and Lignol Tyrrell used to publish Percival s name among the 'prominent physicians' who used and prescribed the J B L Cascade!

Careful study of the Tyrrell "literature" that has been sent out during the past six or seven years is an education in mail-order quackery True to type, there is a series of "follow up" form letters, so prepared as to lead the uninitiated to think that they are individual communications The first of the series comes "in response to your request" and informs you that the "J B L Cascade Treatment" is, in Tyrrell's judgment, "one of the most common sense and practical methods for preventing and relieving most of the diseases known to the world" Tyrrell emphasizes that those who send money for his "treatment" (which includes a "Cascade," a stick of soap and a box of the marvelous "Antiseptic Tonic") will also be 'entitled to unlimited free consultation" Tyrrell modestly adds that as his "reputation is thoroughly established," the purchaser of the "Cascade" secures for himself 'the constant service of a New York specialist"

The second letter of the series still further carries out the deception of making its recipient believe it to be a personal communication, by being written on professional rather than business stationery In this letter Tyrrell declares that he has taken a personal interest in your case" Of course, most people who receive this letter do not realize that it is a stock letter, sent out as a matter of routine and, in all probability never seen by Tyrrell, except when the original order was given for the printing In the third letter of the follow-up series Tyrrell evinces surprise that the victim has not purchased the "treatment' and incidentally obtained 'the advantage of my able advice" This letter makes certain concessions in the price of the treatment and awaits "your valued favors"

With the first of the letters comes a booklet, one of several that Tyrrell sends out to prospective purchasers of his 'treatment," containing among other material a number of testimonials These testimonials are indexed and in the older books the index was said to be "to Diseases Cured by the J B L Cascade Treatment" In the books now being sent, the index is said to be of "Testimonials Showing the Most Astonishing Results Obtained By the Use of the J B L Cascade," etc The older books alleged that Tyrrell's treatment had cured (*vidè* index of testimonials), among many other diseases, "Brain Fever," Consumption, Change of Life (*sic!*), Dysmenorrhea, Gastritis, "Heart Trouble," Insanity, Paralysis and Scarlet Fever The more recent books do not contain the testimonials alleging cures of the conditions just listed, but they give a list that is sufficiently alluring for those sick or near-sick who are in search of a panacea Thus one can go down the list of alleged cures alphabetically from "appendicitis" through "bladder trouble," "delirium tremens" and 'epilepsy" to "kidney trouble," "malaria," "obesity," "rheumatism" and "stomach trouble"

TESTIMONIALS

Some of the testimonials have a serio comic element in them There is, for instance, a panegyric alleged to have been written by Lewis G Spooner, state senator from Minnesota, whose picture adorns the page on which it appears The senator avers that he considers the J B L Cascade "almighty important to any human being past middle age in life," and he considers that possession of the Cascade and use of the same is almighty important" Lillian Russell, looking out from a bunch of roses, asks "Professor Tyrrell" kindly to send her 'two more Cascades and six boxes of the Antiseptic Powder", she wants to take them to Europe Eva Davenport, 'of the Yankee Consul Co " smilingly testifies to the indispensability of the J B L Cascade, which she finds as a vocalist, "invariably cause clearness and purity of tone," besides being of value "in the reduction of obesity" Anna Held roguishly assures '*Mon Cher* Prof Tyrrell" that she is delighted with the Cascade", in fact, she considers "*c'est magnifique!*" One of the latest testimonials purports to be a photographic reproduction of a letter from one Rev Walter W Kent, Cincinnati This testimonial, unlike the others mentioned, is not illustrated —which is a pity The letter-head explains that Rev Kent is "Chaplain, First Ohio Infantry U S V R," and also 'Ex-President Mount Lookout Business Men's Club" Mr Kent offers his "testamonial" (spelling original) because he would not withhold it from his friends 'I often suffer with nervous headaches from brain fag, like most literary people and thinkers do" says Rev Kent A friendly hint to the reverend gentleman A fulsome testimonial for a quackish device is not likely to enhance one's reputation for being either "literary" or a 'thinker"

THE IDEAL COMPANY
239 BROADWAY
NEW YORK.

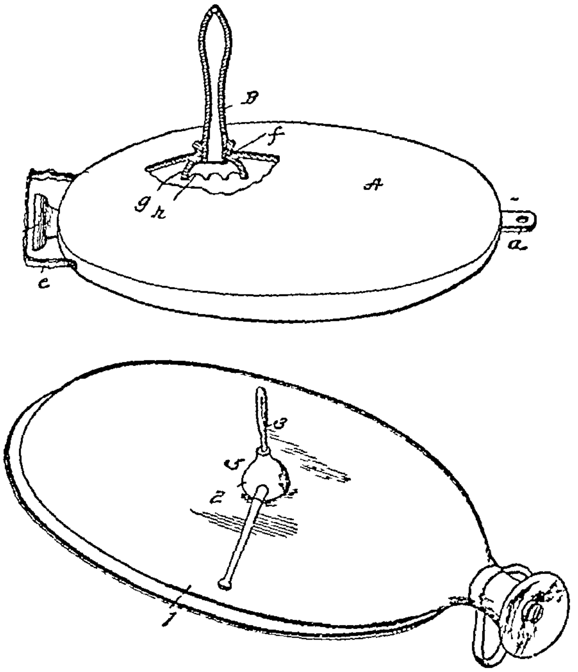
A photographic reproduction (reduced) of an old advertisement of the Ideal Sight Restorer another of Tyrrell s devices

Before leaving the subject of testimonials, reference must be made to a list of physicians published by Tyrrell These men he classes as "distinguished" and "prominent," and claims that they 'both use and prescribe" his "treatment" Investigation shows as might have been expected, that not one of these men can lay claim to being either "prominent" or "distinguished" Professionally, they are nonentities, or worse Some of them are dead, some are apparently not physicians at all, at any rate their names are not to be found in the official records of physicians, one is an ex-"patent medicine" maker, one has advertised 'Obesity, Rupture, Piles Hydrocele and

Varicocele, CURED and GUARANTEED," while others have been commercially connected with Tyrrell and his so-called institute

THE "PATENT MEDICINE" ADJUNCT

Most concerns that sell mechanical devices of a pseudo medical nature have a "patent medicine" as an accessory to the alleged treatment Tyrrell s is no exception His complete treatment" consists in (1) the 'J B L Cascade,' (2) a stick of his famous Rectal Soap" and (3) a box of the Celebrated J B L Antiseptic Tonic" The last is the 'repeater" part of the 'treatment" Tyrrell says regarding the "Antiseptic Tonic"



Tyrrell claims that the J B L Cascade was invented by him The records of the patent office at Washington show that the device was invented and patented by one H M Guild who assigned the patent to the Tyrrell concern The lower of the two devices illustrated above is the Guild instrument—now sold as the J B L Cascade —reproduced from the records of the patent office Tyrrell claims that the J B L Cascade is the only thing of the kind ever specially designed for the purpose for which it is sold the rectal enemas The upper of the two devices illustrated above was invented by a Canadian who obtained a Canadian patent for the device in *1892* and U S patent in *1894*

> This preparation is one of the most important features of the treatment for it attacks and destroys the microbes of disease in their principal breeding place and I cannot too strongly urge the importance of its use for the distruction of these germs prevents disease and hastens a cure'

A woman who had received some of the advertising material sent out by Tyrrell wrote asking why the formula of the 'Antiseptic Tonic" was *not given* Here is what she was told

> Note your comments as to the Antiseptic Tonic and your inquiry as to why we do not give the formula We cannot see any good reason why we should do anything of this kind, and give it to the public in order that they may secure the tonic from the druggist without any profit to ourselves for all time

THE JOURNAL has repeatedly said that the element of secrecy in the 'patent medicine" business is for the purpose of allowing the exploiters of nostrums to make claims that the public would laugh at if it was apprised of the composition of their preparations Tyrrell's "patent medicine" adjunct has been analyzed by the chemists of the American Medical Association Here is the laboratory report

CHEMISTS' REPORT ON THE "ANTISEPTIC TONIC"

J B L Antiseptic Tonic is a dirty white faintly perfumed powder containing small blue particles A 4 ounce package retails for 50 cents Dissolved in water it produces a faintly greenish-blue, turbid solution, having an alkaline reaction to litmus Qualitative tests indicated the presence of a chlorid a borate, sodium, small quantities of calcium and of a sulphate and traces of a nitrate Alkaloids, ammonium salts, free boric acid and salts of copper and zinc were absent

Quantitative determinations indicated that the composition of the specimen examined is essentially as follows

Sodium chlorid (common salt)	69 9 per cent.
Borax	29 6 per cent
Calcium sulphate hydrous (gypsum)	0 5 per cent.
Color and perfume	traces

It seems probable that the gypsum found is not an intentionally added constituent, but that it occurs as an impurity or an adulterant in a cheap grade of borax used in preparing the mixture The insolubility of the gypsum is responsible for the turbidity of the solution

A preparation having all of the "antiseptic" and "tonic" properties of J B L Antiseptic Tonic can be made by mixing 2 8 ounces of salt with 1 2 ounce of ordinary borax at a cost of not to exceed two-thirds of 1 cent

Here, then, we have 2⅘ ounces of table salt mixed with 1⅕ ounce of borax and sold for 50 cents! No wonder Tyrrell "cannot see any good reason" for giving the public the "formula" for his "Antiseptic Tonic" which "attacks and destroys the microbes of disease in their principal breeding place!"

THE TYRRELL ADVERTISING

We have given this much space to a consideration of Tyrrell's brand of quackery because some publications that, in general, show considerable discrimination in the acceptance of advertisements have sold space to the exploiters of the 'J B L Cascade treatment" Correspondence with some of these publications has disclosed an attitude on the subject of quackery that would be laughable if it were not discouraging To the magazines in question "patent medicines," as such are taboo It seems however, that if the alleged "cure" happens to be mechanical rather than chemical in nature, it becomes acceptable, no matter how preposterous the claims made for it may be If the exploiters of the J B L Cascade entirely eliminated from their alleged treatment their salt-and-borax 'patent medicine" accessory, euphemistically referred to as "Antiseptic Tonic," there would still be no valid excuse for accepting the J B L Cascade advertising

The advertisements, "follow-up letters" and other advertising paraphernalia that we have on file, covering several years, show the history of the advertising campaign of the J B L Cascade to have been one of deceit, misrepresentation and quackery While some of the most blatant claims have been modified—due, possibly, to previous criticisms from THE JOURNAL—the advertising still misleads, mispresents and deceives by inference where it does not do it directly In

Photographic reproductions of the letterheads of three concerns of which Tyrrell is or has been president *Health* is the name of a fad magazine published by Tyrrell which carried advertisements of various *pseudo medical products* including Tyrrell s own devices the J B L Cascade and the Ideal Sight Restorer spite of this, the attitude of certain otherwise estimable publications seems to be that taken by the *Christian Herald*, for example, of New York, which, after having the facts brought to its attention by a physician, wrote

> We shall continue to carry this advertisement as we are convinced that the system advocated by Dr Tyrrell is of far greater benefit to the public at large than the medicines prescribed by the average physician'

Summarized, the objections to the exploitation of the J B L Cascade Treatment may be stated thus

1—The key-note of Tyrrell's campaign is his alleged theory that "there is only one disease" and that 'there is only one cause for disease" and that cause 'is auto-intoxication produced by intestinal obstruction" The falsity of these statements and absurdity of the theory are obvious

2—A supplementary feature of Tyrrell's 'treatment" is the 'J B L Antiseptic Tonic," which, it is insisted, is 'one of the most important features of the treatment" The "Antiseptic Tonic" is a secret nostrum sold under ridiculously exaggerated claims at an enormously high price Analysis shows it to consist essentially of a mixture of common salt and borax worth probably two-thirds of 1 cent and sold for half a dollar

3—The administration of rectal enemas by means of the J B L Cascade is not only unscientific, but may in many cases be dangerous The common fountain syringe is both safer and more efficient

4—Tyrrell urges the public to take rectal enemas both in sickness and in health—in other words as a routine part of one's living This advice is mischievous to the point of viciousness

5—Tyrrell misleads the public into believing that prominent and distinguished physicians have approved of and testified to his "treatment" The facts are that not one of the physicians named can, by the widest stretch of imagination be called prominent and distinguished

6—The J B L Cascade is advertised as a veritable cure-all It is claimed that used in sickness any curable disease may be cured, used in health all disease will be prevented!

Correspondence

Lister on the Use of Animals in Research

To the Editor—The following letter was found among Lord Lister s papers by his nephew, Sir Rickman J Godlee (ex-president of the Royal College of Surgeons, England), who is about to publish the authorized Life of Lord Lister I have his kind permission to publish the letter It is a signed holograph letter evidently written and revised with unusual care, for there are many changes and corrections in it It was also evidently copied, for "a line is drawn over it as it was copied' as Sir Rickman informs me The envelope is endorsed 'Rough draft of a letter to Dr Keen" No copy of the letter ever reached me Presumably it went astray in the mail It is of especial interest as showing Lister's deep convictions and personal experience

W W Keen, M D, Philadelphia

12 Park Crescent, Portland Place London W
4 April 1898

My dear Sir—I am grieved to learn that there should be even a remote chance of the legislature of any state in the Union passing a bill for regulating experiments upon animals

It is only comparatively recently in the world s history that the gross darkness of empiricism has given place to more and more scientific prac*tice and this* result has been mainly due to experiments upon living animals It was to the e that Harvey was in large measure indebted for the fundamental discovery of the circulation of the blood and the great American triumph of general anesthesia was greatly promoted by them Advancing knowledge has shown more and more that the bodies of the lower animals are essentially similar to our own in their intimate structure and functions so that lessons learnt from them may be applied to human pathology and treatment If we neglect to avail ourselves of this means of acquiring increased acquaintance with the working of that marvelously complex machine the animal body, we must either be content to remain at an absolute standstill or return to the fearful haphazard ways of testing new remedies upon human patients in the first instance which prevailed in the dark ages

Never was there a time when the advantages that may accrue to man from investigations on the lower animals were more conspicuous than now The enormous advances that have been made in our knowledge of the nature and treatment of disease of late years have been essentially due to work of this kind

The importance of such investigations was fully recognized by the commissioners on whose report the act of Parliament regulating experiments on animals in this country was passed, their object in recommending legislation being only to prevent possible abuse

In reality as one of the commissioners, the late Mr Erichsen informed me no single instance of such abuse having occurred in the British Islands had been brought before them at the time when I gave my evidence and that was toward the close of their sittings

Yet in obedience to a popular outcry the government of the day passed an act which went much further than the recommendation of the commissioners They had advised that the operation of the law should be restricted to experiments upon warm blooded animals but when the bill was considered in the House of Commons, a member who was greatly respected as a politician but entirely ignorant of the subject matter suggested that vertebrate' should be substituted for warm blooded ' and this amendment was accepted by a majority as ignorant as himself

The result is that incredible as it may seem, any one would now be liable to criminal prosecution in this country who should observe the circulation of the blood in a frog s foot under the microscope without having obtained a license for the experiment and unless he performed it in a specially licensed place

It can readily be understood that such restrictions must seriously interfere with legitimate researches

Indeed for the private practitioner they are almost prohibitive and no one can tell how much valuable work is thus prevented

My own first investigations of any importance were a study of the process of inflammation in the transparent web of the frog s foot The experiments were very numerous, and were performed at all hours of the day at my own house I was then a young unknown practitioner and if the present law had been in existence it might have been difficult for me to obtain the requisite licenses even if I had got them it would have been impossible for me to have gone to a public laboratory to work Yet without these early researches which the existing law would have prevented, I could not have found my way among the perplexing difficulties which beset me in developing the antiseptic system of treatment in surgery

In the course of my antiseptic work at a later period I frequently had recourse to experiments on animals One *of these occurs to me* which yielded particularly valuable results but which I certainly should not have done if the present law had been in force It had reference to the behavior of a thread composed of animal tissue applied antiseptically for tying an arterial trunk I had prepared a ligature of such material at a house where I was spending a few days *at a distance* from home and it occurred to me to test it upon the carotid artery of a calf Acting on the spur of the moment, I procured the needful animal at a neighboring market a lay friend gave chloroform and another assisted at the operation Four weeks later the calf was killed *and its neck was* sent to me On my dissecting it the beautiful truth was revealed that the dead material of the thread instead of being thrown off by suppuration had been replaced under the new aseptic conditions *by a firm ring of living* fibrous tissue, the old dangers of such an operation being completely obviated

I have referred thus to my personal experience because asked to do so and these examples are perhaps sufficient to illustrate the impediments which the existing law places in the way of research by medical men engaged in practice whose ideas, if *developed* would often be the most fruitful in beneficent results.

But even those who are specialists in physiology or pathology and have ready access to research laboratories find their work seriously hampered by the necessity of *applying for licenses for all* investigations and the difficulty and delay often encountered in obtaining them

Our law on this subject should never have been passed and ought to be repealed It serves no good purpose and interferes seriously with enquiries which are of paramount importance to mankind

Believe me
Sincerely yours,
Lister

Toxicity of Salvarsan

To the Editor—The cases here reported seem more serious than those recently reported by Ormsby and Mitchell, and Ellis (The Journal, Dec 9, 1916, p 1756) Our technic has always been carefully controlled, and we follow the procedure recommended by the manufacturer No *ill effects* have come to our patients previous to the use of the last two packages of ampules shipped us from New York Out of the last twenty-three injections of neosalvarsan we have had four cases of severe poisoning and one death

In the first case, a woman, aged 21, was given 0 6 gm neosalvarsan, during the *injection* she suffered intense pain in the extremities and a sensation of choking, two hours later she had repeated convulsions, vomited blood, and had a bowel movement every half hour, the abdominal pain was intense, the pulse, 150, temperature, 104, this continued for forty-eight hours, after which she gradually recovered

Since this case, we have had three similar, though less severe than the first

In the last case, Mrs L, aged 43, suffering from syphilitic gumma, was given 0 6 gm of neosalvarsan with no marked reaction, eight days later I injected 0 9 gm of neosalvarsan An hour later, there came a choking sensation, followed by a chill, three hours later, severe vomiting ensued, then involuntary bowel movements, and agonizing pain in the stomach, the body became extremely livid, this lasted three days uninfluenced by treatment, on the third day, the body became purple, the pulse imperceptible, and eight hours later the patient died

Since this case, I have learned that several of the specialists in this city have had cases of severe poisoning from the last shipment of this drug

Dr G J Fields had five cases so severe that he has discontinued the use of either salvarsan or neosalvarsan

Dr F A Goeltz treated six cases of poisoning, all previously injected with the earlier preparation of salvarsan

Dr W L Rich reported two very serious cases of poisoning twelve that had some symptoms of salvarsan poisoning, and eight persons who became only very ill

Claude L Shields, M D, Salt Lake City

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed Every letter must contain the writer s name and address but these will be omitted on request

LEAD POISONING FROM Q BAN HAIR COLOR RESTORER

To the Editor —I have recently seen a case of lead neuritis following the use of a hair color restorer called ' Q Ban made by the Hessig Ellis Drug Company of Memphis Tenn Will you kindly inform me as to whether you have any record of such cases and whether you have an analysis of this preparation showing the amount of lead present?

Lester Adams M D
Eastern Maine General Hospital Bangor Maine

Answer —In May, 1915, Dr E B Markey of Dayton, Ohio, reported untoward effects from the use of Q-Ban Hair Color Restorer" in two cases that came under his observation In both cases the victims 'developed a moderately severe dermatitis of the forehead, neck and face' following the use of the preparation "Q-Ban Hair Color Restorer" was analyzed by the Connecticut Agricultural Experiment Station and the results reported in the Annual Report of 1915 According to this report the product had the following composition

Alcohol by volume	10 46 per cent
Solids	16 39 gm per 100 c c
Glycerin	11 56 gm per 100 c c
Free sulphur	3 08 gm per 100 c c
Lead acetate	1 68 gm per 100 c c
Oil of rose geranium	present
Salicylates resorcin alkaloids	none

The Connecticut chemists, in summarizing the results of their work said 'This is a perfumed, alcohol-glycerin solution of 1 68 gm per 100 c c of lead acetate, containing 3 08 gm of free sulphur in suspension It is simply one of the many familiar lead acetate-sulphur preparations, and its use is by no means free from danger'

TREATMENT OF ARTHRITIS DEFORMANS

To the Editor —Is there anything worth while medicinally, in the treatment of arthritis deformans after such *focal infections as tend to causation* have been removed? I have a patient a girl 21 years old who has had arthritis deformans for a year her father has had it for twenty years It is possible that I have overlooked the recent literature on the latest methods of treatment

E F Fischer M D, Alton, Ill

Answer —The treatment of arthritis deformans involves a number of factors There seems to be no question that the initial damage to the joints in many cases is accomplished by infection derived from some focus in the body Bacterial invasion of joints may be intermittent, so that new joints are successively involved, and exacerbations occur in those previously affected The source or sources of this infection should of course be sought for and, if found, removed But *when the patient* seeks relief, presenting the clinical picture of some one of the types of arthritis deformans, the anatomic changes in the joints, such as the formation of granulation tissue, villous excrescences from the synovial surfaces, the erosion of cartilage, new bone formation about the margins of the articular surfaces, and the relaxation of the joint ligaments are more or less advanced These changes have resulted not alone from infection, but also from the continued trauma of use acting on injured joint surfaces It is evident, therefore, that the mere removal of the original cause of these changes cannot appreciably modify the existing lesions of joints, further than to prevent the invasion of new joints But much can still be accomplished for these patients It is important to consider the special needs of each In one instance important joints may have become ankylosed in unusable positions, or their motion interfered with by marginal exostoses Appropriate surgical treatment will be of service in such cases Other joints are benefited by immobilization with splints or adhesive tape Continued infection pain and interference with locomotion may have resulted in partial invalidism, with attendant anemia, poor appetite and sluggishness of function of various organs of the body With the removal of infection and all possible mechanical correction of deformities should go attention to nutrition by giving a well balanced general diet Tonics containing iron may be of benefit There is no drug therapy specific for this condition although some simple form of iron may be of benefit Outdoor life and such moderate exercise as is consistent with the policy of rest for affected joints will help to build up the general tone of the patient

INTRAVENOUS INJECTION OF QUININ

To the Editor —1 Please give the latest technic on quinin administration by the intravenous method

2 Is it safe to give from 5 to 10 grains of the dihydrochlorid in 1 c c sterile saline or distilled water intravenously?

3 Please give the latest technic of quinin administration by the intramuscular method

Kindly omit name P H C

Answer —1 The technic of the injection is the same as that of other intravenous injections such as of neosalvarsan

2 The formula suggested (from 30 to 60 per cent) is far too concentrated for intravenous injection Baccelli, the originator of the method recommended a 10 per cent solution Present opinion, however regards even this as much too strong Deaderick ('Endemic Diseases of the Southern States" 1916) recommends a 1 per cent solution Recently Witherspoon (*Southern Medical Journal*, December, 1916) reported the results of several injections of 10 grains of dihydrochlorid in 15 c c of water, approximately a 5 per cent solution Practically all of the patients reacted severely to such injections The dose which our correspondent mentions is correct The mixing of the metric and the apothecaries systems of weights and measures should be avoided, it is apt to lead to confusion

3 Parenteral administration of quinin is heroic, see "Hypodermic Injection of Quinin," Queries and Minor Notes, The Journal, Dec 30, 1916, p 2030

THE NATIONAL BOARD OF EXAMINERS—RECIPROCITY

To the Editor —1 What are the requirements that one must have to take the examination by the National Board of Medical Examiners or where can I obtain this information? 2 What is the scope of the national board as regards recognition by all the states? 3 Please inform me where I can get a pamphlet or booklet on reciprocity

Kindly omit name L F P

Answer —1 Candidates who graduated since 1912 (*a*) must have completed two years of acceptable college work, including physics chemistry, biology and a modern language, based on a four year high school education, (*b*) must have graduated from a medical college rated in Class A by the American Medical Association, and (*c*) must have spent at least one year in an acceptable hospital as an intern or in a laboratory For those who graduated prior to 1912 the board may accept equivalent credentials Further information and application blanks may be obtained from the secretary, Dr J S Rodman, 2106 Walnut Street, Philadelphia

2 The states in which the boards have thus far announced their willingness to recognize the certificates of the national board are Colorado Idaho, Iowa, Kentucky, Maryland, New Hampshire, North Dakota and Pennsylvania

3 Information regarding reciprocity is contained in a book of "Laws (Abstract) and Board Rulings" published by the American Medical Association The price is 30 cents

LITERATURE ON INFANTILE PARALYSIS

To the Editor —It falls to my lot to give a talk on infantile paralysis before a club and I wish to review some of the latest work done in this line I would consider it a great favor if you would tell me where I can get this information M D, Iowa

Answer—The following is a list of references on this subject

Sophian Abraham Municipal Control of Infantile Paralysis The Journal Aug 26 1916, p 669
Ryerson Operative Treatment of Deformities Due to Poliomyelitis *Am Jour Orthop Surg* February 1916

WEIL FELIX DIAGNOSTIC REACTION IN TYPHUS

To the Editor —What is the new Weil Felix reaction? F E

Answer—This reaction was described by Weil and Felix in the *Wiener klinische Wochenschrift*, Nos 2, 28 and 31, 1916 but none of these numbers have happened to reach us From references to the reaction in periodicals which have come through recently, it seems that Weil and Felix succeeded in isolating from typhus material a proteus-like germ which gives a specific agglutinating reaction with the serum of typhus patients They cultivated this germ from the urine and blood of typhus patients in a total of thirty-four cases, and never succeeded in cultivating it from other patients The agglutinins for this reaction do not develop much before the sixth day, but the reaction persists pronounced from then onward until defervescence, when it promptly disappears No constant connection between this agglutination and the Widal agglutination could be detected, and in diseases other than typhus there is no agglutination with the Weil-Felix technic, or it takes hours to occur instead of the rapid response in typhus One writer reports that the Weil-Felix strain agglutinated at 1 50 up to 1 1 600 with typhus serum, while there was no agglutination with other patients even at 1 20

PURPURA HEMORRHAGICA

To the Editor —1 Please inform me concerning the latest treatment and its results in purpura hemorrhagica

2 Has autoserum ever been used? If so, with what success?
George H Sciaroni M D Sutter Creek Calif

Answer—1 Present opinion seems to favor the employment of blood or serum injections in some form for the treatment of this disease A full discussion of the treatment of this disease will be found in an article by Fmsheimer published in The Journal Jan 1 1916, p 20 The following are the conclusions of this article

> The best methods of treatment of purpura hemorrhagica in addition to the usual measures are (*a*) subcutaneous or intravenous injection of human blood serum (*b*) transfusion and (*c*) intramuscular injection of whole fresh human blood
>
> The intramuscular injection of whole blood is a simple harmless effective procedure and should be employed before other radical measures in all cases of severe purpura hemorrhagica

A case successfully treated with horse serum is reported in The Journal, April 1, 1916, p 1020

2 No reports are available of cases in which the patient s own serum has been used

NINE USEFUL DRUGS

To the Editor —As a subscriber to your valuable publication I write to know if you have ever published your symposium on Nine Useful Drugs' as inquired about in your issue of July 22 1916? If so when did it appear? Edward C Tingley D O, Los Angeles

Answer—Only eighteen replies were received to the original question, hardly enough to make an analysis worth while We again repeat the question in the hope that sufficient answers, at least 100, will be received The question follows

To the Editor —In my grip which I carry with me I have a case of nine medicine bottles Would you make a suggestion as to the most useful drugs to carry with me? Morrell Simpson, M D —— Ind

University Medical College of Kansas City	(1903)	Kansas

Book Notices

Dyke's Automobile and Gasoline Engine Encyclopedia Treating on the Construction Operation and Repairing of Automobiles and Gasoline Engines By A L Dyke E E Fifth Edition Cloth Price $3 Pp 717, with 366 illustrations St Louis A L Dyke 1916

The motor car has become almost a necessity to the physician—certainly as much so as was the horse and buggy a decade ago And probably the same proportion of physicians take care of and drive their own machines as formerly drove their horse-drawn conveyance To take care of and drive an automobile with any satisfaction, it is essential to know at least the general principle of the inner combustion engine and the various mechanical devices which are necessary to transmit the power generated by the gasoline explosion so that it will turn the wheels of the automobile Dyke's "Automobile and Gasoline Engine Encyclopedia" explains all this in such a clear, simple form that any one will understand it The book is elaborately illustrated, and the only fault with it—if this could be considered a fault—is the detail in which practically every part of the mechanism and every principle is explained

Syphilis and the Nervous System for Practitioners Neurologists and Syphilologists By Dr Max Nonne Chief of the Nervous Department in the General Hospital Hamburg Authorized Translation *from the Second German Edition by* Charles R Ball M D, Chief of the Nervous and Mental Department St Paul Free Dispensary Second American Edition Cloth Price $4 Pp 450 with 98 illustrations Philadelphia J B Lippincott Company, 1916

This is the second American edition, presumably a translation from the third German edition of this work, it is practically the same as previous editions, except that a chapter on salvarsan therapy has been added The author is essentially a clinician While the book is really an extensive review of our present knowledge of syphilis of the nervous system, it contains the views of leading neurologists and syphilographers and covers the pathology very well The greatest usefulness of the work lies in its value as a guide to the practitioner With the introduction of salvarsan and of intraspinal injections, the therapy of syphilis of the nervous system has undergone so many modifications that it is entirely impossible for any textbook to present a complete and up to date statement of the present status of the treatment of syphilitic diseases of the nervous system In this respect the present book perhaps attains all that can be expected of it As not infrequently happens in later editions some of the more recent statements need to be harmonized with those in older portions of the text, or, rather, some of the former statements need to be eliminated entirely While the book is not without some minor defects, it is perhaps quite the best thing in English covering the subject of which it treats The translator has done his work well, although in places he has not succeeded in getting away from the German idiom and occasionally is too literal

I K Therapy (Immunkorper Immune Substances) in Pulmonary Tuberculosis with a Summary of Cases By William Barr M D D Sc D P H District Tuberculosis Officer for the West Riding of Yorkshire Cloth Price $1 25 net Pp 82 New York William Wood & Co, 1916

In order to overcome the apathy toward Spengler's Immunkorper therapy to set forth the benefits that have been obtained therewith, and incidentally to point out mistakes occurring in its use, the author makes this contribution purely on a clinical basis It is written in a rather generalized form and considers dosage, reactions, suitability of cases for treatment, contraindications, and effects and results of treatment A summary of the results in forty-seven ambulant cases treated by the author is given The book is written in extremely simple form, probably with a view to appealing to the general practitioner, and the author is easily misled by the psychology of the patient, as attested by a paragraph on page 52 ending 'and, after all, it is the patient who is the final judge (meaning of the efficacy of the treatment) Only such data as the weight of the patient, the temperature and the amount of sputum are used as criteria in judging the efficacy of I K

Social Medicine, Medical Economics and Miscellany

TREPONEMA PALLIDUM AND SPIROCHAETA PALLIDA

From the Standpoint of the International Rules of Zoological Nomenclature

CHARLES WARDELL STILES, M D
Professor of Zoology U S Public Health Service
WASHINGTON, D C

THE JOURNAL,[1] Nov 25, 1916, contained an exceedingly interesting and scholarly article by Dr Pusey of Chicago, dealing with the nomenclature of the protozoon of syphilis and showing in its composition an elaborate amount of bibliographic study Copies of THE JOURNAL in question had been in Washington but a few hours when suggestions reached the office of the International Commission on Zoological Nomenclature that the case be discussed from the standpoint of the international rules The latter fact evidences the point that despite the care with which Dr Pusey prepared his brief, there are some features of the subject which he did not include in his discussion, and it is in compliance with the suggestions mentioned that the present manuscript is prepared

Before the nomenclatorial premises are set forth and the rules applied, and to make the general subject clearer to nontaxonomists, it will be well to explain certain differences of opinion as to generic concepts

THE OLDER AND THE NEWER VIEWS OF GENERIC LIMITS

Workers in systematic zoology and systematic botany may be divided into two general classes those who favor broad genera with many species, and those who favor small genera with fewer and very closely allied species The former are known as the "lumpers," because they "lump" many species into one generic group, the latter are called "splitters," because they split up the genera into small and allegedly more homogeneous groups

For instance, a "lumper" might consider that all of the tapeworms possessing four suckers should be placed in one and the same genus, *Taenia*, while a "splitter" would recognize *Taenia* (for species of the type of *T solium*), *Hymenolepis* (for species of the type of *T diminuta*) *Dipylidium* (for species of the type of *T canina*), *Davainea* (for species of the type of *T proglottina*), etc Or to take another example, a "lumper' of the old school might unite the field mice, the house mouse, the rats, and the guinea-pigs in the genus *Mus*, while a 'splitter" of the newer school would consider that the rats are much more closely related to each other and to the house mouse than they are to the field mice and the guinea-pigs, accordingly he would express this evolutionary or blood relationship by dividing the old genus *Mus* into a number of genera, and by uniting these genera into subfamilies, families superfamilies, etc in order to give what he calls a "natural" as distinguished from an artificial" classification Thus, a genus, from the standpoint of a "lumper," might be a family or even a superfamily from the standpoint of a "splitter '

These two points of view are determined by two factors in particular first, by different opinions as to whether given anatomic characters are of specific, subgeneric, generic, or supergeneric value, and, second by the existing knowledge in any given decade in respect to the details of the anatomy of the different species

The second factor mentioned, increase in anatomic knowledge as years advance, has a natural tendency to cause later systematists to divide and subdivide the genera of earlier authors The first factor, different opinion as to the classificatory value of various characters in respect to formation of systematic units of higher or of lower rank, is dependent on several points, notably, however on the fact as to whether an author has studied a relatively small number or a relatively large number of different organisms of various groups and, further, on the fact whether his special training has been on the taxonomic side or on the biologic side of these organisms

In harmony with the foregoing generalizations, it may be expected that medical authors (who have to deal with relatively few different kinds of organisms) will be predisposed to become ' lumpers," as were the earlier zoologists and earlier botanists, while modern systematic zoologists and modern systematic botanists (who have to classify a very much greater number of organisms) will show a predisposition to array themselves on the side of the "splitters"

These conditions are inevitable in science and must be accepted with equanimity That the entire tendency in taxonomy today is, and for more than half a century past has been, toward the point of view of the "splitters" will be evident to any person who studies nomenclature extensively That medical literature is and always will be from five to ten years back of zoological and botanic literature in admitting and adopting the finer points of generic concepts in zoology and botany seems equally clear

Applying these generalizations to *Spirochaeta* and *Treponema*, a 'lumper" would unite a large series of free-living and parasitic forms in the old genus *Spirochaeta*, while a splitter" would divide these organisms into several groups (genera) at the same time uniting into each of the restricted genera the species which he considers most closely related to each other In these differences of opinion it is natural to expect that the tendency of the medical authors will be toward the point of view of the 'lumpers," while that of the zoologists (as illustrated by Schaudinn) will be toward the point of view of the splitters"

THE NOMENCLATORIAL DIFFICULTIES

Dr Pusey in his interesting and learned article, practically takes the point of view characteristic of a number of authors namely, that the choice between two names is to be determined by the preponderance of the use of one or the other of these names This view is not entirely in harmony with that held by the vast majority of systematists, who are the authors on whom the greatest burden of systematic names falls As zoologists are obliged to handle hundreds of thousands of systematic names, and to keep them as clear as possible despite the change of views in respect to classification from one decade to the next, the zoological profession has seen itself forced to formulate rules for guidance in accepting changing, and rejecting names For a number of years different countries had different sets of rules, but finally the International Zoological Congresses have succeeded in establishing a series of international rules which are under the care, so to speak, of an international commission of eighteen professional zoologists selected from various countries These commissioners are elected in three classes of six men each Each class serves nine years, and the term of one class expires every third year The international rules are published in English, French German, and Italian and the 'Opinions" of the commission are published by the Smithsonian Institution

It is an undeniable fact that not every zoologist considers himself bound by these rules as it is also a fact that not every physician considers himself bound by the medical code of ethics, but the rules have been adopted by the International Congress, and thus they are the formal expression of opinion of the organized zoological profession

As a legalized practitioner of medicine, I would submit the claim that if a physician calls into consultation a zoologist, the latter becomes for the moment a quasimember of the medical profession, and in matters concerning the patient this zoologist is bound by the code of ethics as adopted by the organized medical profession

Conversely, as a professional zoologist, I would submit that when a physician enters the field of zoological nomenclature he should consider himself subject to the rules as adopted by the organized zoological profession, rules that have been established for the good of all persons concerned

---

THE NOMENCLATORIAL PREMISES IN THE CASE OF TREPONEMA PALLIDUM AND SPIROCHAETA PALLIDA

In considering competitive names we must first have before us certain premises, in particular the dates of publication and the genotypes (or type species) for the genera under consideration

The dates of publication are important when it comes to the application of the law of priority

The expression "genotype" or "type species" is relatively little known in medical literature, and must therefore be explained

There have been about 1,500 or more specific names used with the generic name *Taenia* since 1758 Assume that we wish to divide the numerous species thus represented, into ten or into 100 more restricted genera the question immediately arises as to where the name *Taenia* belongs Every generic name is supposed (theoretically) to be based on a single species its nomenclatorial genotype or type species and if the genus is divided the original name goes automatically to that subdivision which contains the type species (namely, *Taenia solium* for the generic name *Taenia*), so that no matter how differently authors may classify the various species, every author is obliged under the rules to apply the name *Taenia* to the restricted group to which he assigns *Taenia solium*

The points which come into consideration in determining which species is genotype for a given generic name are elaborately worked out in Article 30 of the international rules

The nomenclatorial premises for the case now under consideration are as follows

In 1834 Ehrenberg proposed *Spirochaeta* as a new genus basing the same on the single species *S plicatilis* described in the same paper, with Berlin Germany, as its type locality where it is a free-living organism in water Article 30 (*c*) reads "A genus proposed with a single original species takes that species as its type (Monotypic genera)" Accordingly, *S plicatilis* is the genotype of *Spirochaeta*

In 1841 Dujardin changed the spelling of the generic name to *Spirochoeta* and in 1872 Cohn changed it to *Spirochaete* Both of these new modes of spelling are known as "variants," and they are dependent on the same type species as the original name *Spirochaeta*

From 1834 to 1905, a considerable number of minute spirochete-like organisms were described by various authors, who placed the species in question in the genus *Spirochaeta* 1834 This was a perfectly proper procedure from the point of view that their major characters were identical with the characters interpreted as major characters of *S plicatilis* As the genus grew in size by the addition of various organisms, it became evident from the point of view of certain authors that what had been interpreted as major generic characters were probably characters of supergeneric (as family) rank, and in accord with this view several authors have selected certain species which were included by earlier writers in the genus *Spirochaeta*, have designated them as type species of new genera, and have assembled around these type species other species which they consider more closely related to the respective genotypes than to *S plicatilis*

Vuillemin, for instance, June 5, 1905, proposed the new genus *Spironema*, basing it on *Spirochaeta pallida* Vuillemin was not aware of the fact that the name *Spironema* had been given in 1864 to a genus of mollusks

Article 34 of the International Rules reads as follows

> A generic name is to be rejected as a homonym when it has previously been used for some other genus of animals Example *Trichina* Owen 1835 nematode is rejected as homonym of *Trichina* Meigen, 1830 insect (See Opinions 12 and 19)

According to Article 34, just quoted *Spironema* 1905 is an absolute homonym of *Spironema* 1864 and is automatically rejected on this account

Schaudinn noticed that the name of *Spironema* 1905 was not available under the rules, and he proposed the name *Treponema* as substitute, basing the name on the species *Spirochaeta pallida* The name *Treponema* was published, Oct 26, 1905

Stiles and Pfender, also, independently of Schaudinn, noticed that *Spironema* 1905 was preoccupied by *Spironema* 1864, and they published, Dec 2 1905, the new generic name *Microspironema*, basing it on *Spirochaeta pallida* The law of priority, namely, Article 25 of the international rules, reads as follows

> The valid name of a genus or species can be only that name under which it was first designated on the condition (*a*) that this name was published, and accompanied by an indication, or a definition, or a description and (*b*) that the author has applied the principles of binary nomenclature (See 'Opinions' 1, 2, 4, 5 9, 10, 12 13, 15 17 19 21 24, 28 37 40 46, 49 54 56)

Accordingly, *Microspironema* of Dec 2, 1905 automatically falls as an absolute synonym of *Treponema* of Oct 26, 1905

It now remains to consider *Spirochaeta* 1834 and *Treponema* 1905 As shown in the foregoing, *Spirochaeta* 1834 has for its genotype a free-living organism (*S plicatilis*), while *Treponema* has for its genotype an obligatory parasitic organism (*T pallidum*), with man as the type host These two organisms differ in certain anatomic, physiologic, and biologic characters

We now have a very clear cut and simple nomenclatorial proposition before us, but the decision finally rests on the point whether we are "lumpers" or "splitters"

If we belong to the "lumpers" and hold that *Treponema pallidum*, an obligatory parasite is congeneric with *Spirochaeta plicatilis*, a free-living organism, it is incumbent on us, under the rules, to express our view on the classification by the nomenclature we use and thus to adopt the name *Spirochaeta pallida*

If, on the other hand, we belong to the "splitters," and hold that the spirochetes represent a heterogeneous mass of species which in the interest of clarity of classification should be assembled into more restricted and more natural generic groups, it is incumbent on us to confine the name *Spirochaeta* to organisms showing the major characters of *S plicatilis* *Cristispira* to organisms showing the major characters of *S balbianii* and *S anodontae*, *Treponema* to those showing the major characters of *S pallida*, *Spiroschaudinnia* to those showing the major characters of *S recurrentis*, and so on through all of the restricted groups we wish to recognize

Thus, not entirely in harmony with the view expressed by Dr Pusey, namely, that authors who use *Treponema* do so out of deference to the memory of Schaudinn, these authors are in reality "splitters," who are acting entirely in accord with the international rules

The practical question remains as to what course is best for an author who prefers not to express an opinion on the strictly taxonomic side of the problem

Several courses are open to him

1 He may adopt either name and quote the other in parentheses, as *Spirochaeta pallida* (*Treponema pallidum*) or *Treponema pallidum* (*Spirochaeta pallida*) It will suffice if he gives either of these double citations only once in his article, namely, the first time he mentions the technical name After that he will do well to use consistently either the one or the other, but not both binomials

2 He may use either name explaining in a footnote that he does not commit himself to any taxonomic interpretation

3 He may take an intermediate position between the "lumpers" and the "splitters" by recognizing *Treponema* as a subgenus of *Spirochaeta*, and in this case he writes *Spirochaeta* (*Treponema*) *pallida*

POSSIBLE COMPLICATION OF BIOLOGIC DATA

There is a point, however, which it is wise for authors to recall In discussing biologic data, as in life histories, cultural methods, etc, it is much more difficult to separate data which are confused under one generic name than to unite data which are well defined under two generic names Far-sightedness lies in keeping biologic data as distinct as possible Applying this principle to taxonomic units, the more progressively conservative plan is to adopt restricted rather than broad units if one is in doubt as to the name to be used Specifically, if the biologic data concerned in *Treponema pallidum* become confused with the biologic data involved in *Spirochaeta plicatilis*, it will, in all probability, be very much more difficult later to divide the data between *Treponema* and *Spirochaeta* if both are classified now as congeneric than if they are now classified as generically distinct, for the reason that many authors, in discussing these data, will use the name "spirochetes" instead of the specific names *S plicatilis* and *S pallida,* and as one author quotes from another, year after year, confusion will increase in this case as it has in other cases

From this point of view, even if from no other, it appears more far-sighted to adopt at present the name *Treponema* for *T pallidum*

As this article is intended simply to present the nomenclatorial points at issue, I refrain from entering into a discussion of the more strictly zoological points as to the characters which have induced certain zoological authors to recognize *Treponema* as of generic rank, distinct from *Spirochaeta*

I believe, however, that it is entirely consistent with the nature of the discussion to add that my experience in zoological nomenclature, not only as a systematist, but especially as a member of the International Commission since 1895, has thoroughly persuaded me of the wisdom and conservatism (from the point of view of the future) of using restricted generic groups in preference to larger heterogeneous genera, and that in case of doubt it is, in general, the better course to accept a restricted generic name, especially when discussing its genotype

For instance, if I were seriously in doubt as to whether *Treponema* should be considered generically distinct from *Spirochaeta,* I should accept *Treponema* for *T pallidum* and its closest allies, on the practical ground that this course is much less likely to result in later confusion in respect to biologic and bibliographic data in case subsequent work proves to the satisfaction of the "lumpers" that *Treponema* should be recognized as distinct from *Spirochaeta,* but I should, in that case, quote *Spirochaeta* at least once in my article in a way to indicate to systematists that I was aware of the difference of opinion which exists among authors

The case under discussion is not unlike that of *Endamoeba histolytica* A "lumper" might consider *Amoeba histolytica* congeneric with *A limax, A proteus,* etc, but a "splitter" would consider it more exact and more practical to recognize *Endamoeba histolytica* and *Vahlkampfia limax* as generically distinct from *Amoeba proteus* (*seu Chaos chaos*)

The question whether the literature of any particular group of men uses *Amoeba* or *Endamoeba* would not be the determining factor in the nomenclature of the group

From the foregoing it will be clear, I hope, that the question of sentiment is not recognized by the international rules

In his last paragraph Dr Pusey says, "If the best usage means anything, *Spirochaeta pallida* is an acceptable term for the organism of syphilis" In this connection it may however, be pointed out that our conception as to what is best usage depends largely on the question whether we are 'lumpers" or "splitters" Best usage from the point of view of the splitter is that usage which comes closest to expressing a natural classification of the organisms, and this is a question which will eventually be based on consensus of opinion by taxonomists who deal with large numbers of organisms, both free living and parasitic

If it can be shown that it "will produce greater confusion than uniformity" to use *Treponema* instead of *Spirochaeta,* it would be within the power of the International Commission to suspend the rules in this case and to apply *Spirochaeta* to the treponemes, instead of to the spirochetes typified by *S plicatilis* even if authors universally agree that *S plicatilis* and *T pallidum* are not congeneric, but unless it can be shown that the application of the rules will produce greater confusion than uniformity authors who consider *T pallidum* generically distinct from *S plicatilis* have no argument which would justify them in continuing to use *Spirochaeta pallida* in place of *Treponema pallidum*

SUMMARY

1 Any author who considers *Spirochaeta plicatilis* congeneric with *Treponema pallidum* is expected to express this view in his nomenclature by using *Spirochaeta pallida* as the name for the organism of syphilis

2 Any author who considers that *Treponema pallidum* is generically distinct from *Spirochaeta plicatilis* is expected to use the name *Treponema pallidum*

3 This is not an editorial question, but one of nomenclature based on taxonomic concepts, and it will be finally settled on the basis of ultimate consensus of opinion by systematists as to the generic limits of *Spirochaeta,* type *S plicatilis*

4 In case of doubt, and pending final settlement, it is clearly better, in order to keep biologic data as distinct as possible, to follow Schaudinn in using *Treponema* as generic name for the organism of syphilis The use of *Treponema pallidum* precludes confusion, the use of *Spirochaeta pallida* need not necessarily result in confusion, if all authors quote the specific as well as the generic name, but it invites confusion because so many authors shorten the technical name to "spirochetes"

5 A position intermediate between the "lumpers" and the "splitters" may be taken by recognizing *Spirochaeta* as a genus containing certain subgenera (*Spirochaeta* s str, *Treponema,* etc) If this intermediate position is preferred, the proper citation of the organism of syphilis would be *Spirochaeta* (*Treponema*) *pallida*

6 If a vernacular name is desired for *Spirochaeta (Treponema) pallida,* "treponeme" is likely to keep biologic data differentiated more clearly than will the name "spirochete"

[Dr Pusey s discussion of Dr Stiles reply will appear in this department next week]

Practical and State Medicine

In his address to the students at the opening of the medical school of the University of Michigan in October, 1916 (*Science,* Dec 8, 1916, p 799), Prof Victor C Vaughan in expressing his views of the needs of the present and of the future of practical medicine, said

The greatest need of practical medicine today is more and better equipped hospitals With these the specialist and the skilled nurse will multiply and improve Such hospitals should be supplied with thoroughly equipped and competently manned diagnostic laboratories which should serve not only curative but also preventive medicine Water and milk supplies should be examined daily, and visiting nurses under the direction of a competent health officer should constantly patrol the community Adjunct dispensaries which should serve as schools of instruction in baby feeding and care, child welfare home sanitation and everything pertaining to healthy living should supplement the community hospitals When in addition to these agencies the people generally can be educated to see the benefits that would follow the periodic thorough examination of all in order to detect the first departure from the normal, then medicine will be able to render its highest service to mankind

It must be evident that if these hopes are to materialize, the practice of medicine must become more and more a state function That the tendency is in this direction, and that this should be encouraged for the public good, are not matters of doubt in my mind Only a few years ago some of the most eminent men in the profession combated earnestly state support of medical education They claimed that the state had no right to establish and maintain medical schools, and that such aid was not fair in competition with the proprietary schools, which at that time educated more than 90 per cent of the annual recruits to the profession Now, no one questions either the right or the duty of the state to establish and support medical schools, while the proprietary schools, having proved wholly inadequate and inefficient, have practically ceased to exist Even the man in the street sees the advantages which have resulted from these changes To state that a medical school is a proprietary one, in the sense generally understood by that term immediately condemns it with intelligent men Courts from the lowest to the highest in the land have uniformly held that the state has the right to maintain its own medical school, and also to pass on the merits of other schools both within and without its borders, to set up standards of medical education, to define the requirements of admission to medical schools, to submit those who wish to practice within its borders to certain intellectual and moral tests in order to pass on their professional fitness, and to revoke the licenses of the unworthy

Medicolegal

There Must Be Some Imprisonment for Illegal Practice — As to Residence

(Rutherford vs State (Texas), 187 S W R 481)

The Court of Criminal Appeals of Texas reverses a judgment against defendant Rutherford, who was convicted of unlawfully practicing medicine and his punishment assessed at a fine of $100 The reason given for this reversal and remanding of the cause is that Article 756 of the Penal Code of Texas provides that the punishment for unlawfully practicing medicine shall be by fine of not less that $50, nor more than $500, and by imprisonment in the county jail for any period of time not exceeding six months It is thus seen that the legislature has fixed some imprisonment as a minimum punishment the jury can assess The punishment assessed must be always within the minimum and maximum fixed by law This court and no other court in the state, can assess a punishment that the law does not authorize

Another thing should be mentioned While the trial court did not err in overruling a motion to quash the indictment on the grounds presented in the motion, yet the court of criminal appeals thinks that on another trial the indictment either should allege and the proof show that the defendant was temporarily residing in Johnson County if such was the fact, or if this was not the fact, then, as it was alleged that his residence was unknown the indictment should not only allege that he had not recorded a certificate authorizing him to practice in Johnson County but should further allege that he had no certificate authorizing him to practice, and proof that he had recorded no certificate would be prima facie proof that he had none by virtue of the statute

Sufficiency of Complaint and Validity of Provisions of Medical Practice Act

(Piper vs State (Wis) 158 N W R 19)

The Supreme Court of Wisconsin, in affirming a conviction of Defendant Piper of practicing medicine without a license, holds that the complaint did not fail to state an offense and was not fatally defective because it did not set forth the classes of medical and surgical practitioners exempted from the law The exemptions specified by Section 1435d, Statutes of 1915, are in a separate section, and need not be specified in the complaint These are defensive matters Nor was the complaint defective because it charged the commission of the offense on 'information and belief"

It was contended that the provisions of Section 1435, Statutes of 1913, arbitrarily attempt to define what is to constitute the practice of medicine and surgery, and condemns practices which do not, in substance, constitute the practice of medicine and surgery, and hence deprive persons of rights guaranteed them by Section 1, Article 14, of the federal constitution, and Sections 5 and 11, Article 1, of the state constitution The defendant claimed on this point that the provisions of Section 1435f Statutes of 1913, penalizing all persons who shall append to their names the words or letters "Doctor, Dr, Specialist, M D, D O or any other title, letters, combination of letters or designation which in any way represents him or her, or may tend to represent him or her, as engaged in the practice of medicine surgery or osteopathy in any of its branches, or who shall for a fee or for any compensation of any kind or nature whatsoever, prescribe or recommend for like use any drugs or other medical or surgical treatment or osteopathic manipulation, for the cure or relief of any wound, fracture, bodily injury, infirmity or disease,   " are an arbitrary and unlawful classification as medical and surgical practitioners of persons who are not necessarily engaged as such practitioners, and thus deprives them of the liberty to do these things, contrary to their constitutional rights The contention overlooked the provision that the use of the words or titles so appended to *a name* is denounced by the law whenever they represent, or tend to represent, the person as a practitioner or medicine, surgery or osteopathy, *or if he as* such a practitioner does anything by way of treatment or gives a prescription for a fee All the prohibited acts are limited to persons who in fact do these things as practitioners of medicine, surgery or osteopathy When so applied, these regulations have been repeatedly held to be within the legislative power The court discovers nothing in these provisions which conflicts with the right of trial by jury in cases arising under the law The statute is a proper one for the regulation of the practice of medicine, surgery or osteopathy, and the provisions accomplish this purpose in a reasonable way

Requisites to Making Married Woman Liable for Medical Services for Son

(Davenport vs Rutledge (Texas) 187 S W R 988)

The Court of Civil Appeals of Texas, in reversing a judgment obtained by the plaintiff in this case on account for services rendered by him as a physician to the defendant s minor son, who had been injured by a railroad, says that at the time of the alleged services the defendant's husband was alive, and he and the defendant were living together as husband and wife The child was their offspring, living with them In order to make the defendant—the wife—personally responsible for the services, she must have entered into a contract with the plaintiff for services rendered necessary to her child If there was no such contract, and she only acquiesced or consented for the physician to treat the child this would not bind her personally or make her separate property liable It is not sufficient that she merely give an order or call in a physician, for in such case the presumption is that she does so as the agent of her husband whose duty it is to supply such things After the services were rendered, a mere verbal promise on her part to pay would not render her separate estate liable for the debt of the community, as it is called She would not be bound personally for the default of her husband by such verbal promise to pay his debt If the testimony of such verbal promise was admissible at all it was admissible only as a circumstance on the question whether she contracted for such services in the first instance A liability could not be founded against her on such verbal promise, made after the debt accrued, and if the judgment reversed was based on such promise, it was erroneous and without legal testimony Her mere acquiescence or consent for the physician to treat her child would not support the judgment

AMERICAN SOCIAL HYGIENE ASSOCIATION, CENTRAL STATES DIVISION

Joint meeting with Chicago Women s Club Woman s City Club and Chicago City Club with the Chicago Medical Society participating held at Chicago Dec 14 1915

Dr William T Belfield, Chicago, in the Chair

SYMPOSIUM ON SYPHILIS

The Campaign for Social Hygiene

Dr William T Belfield, Chicago Fifty years ago personal liberty assured to every one the right to contract scarlet fever and diphtheria and scatter it among his fellows without interference by law The city did, however, recognize the duty of seeing that the remains were decently interred Today personal liberty assures to every one the right to contract syphilis or gonorrhea and to communicate it to his intimates, or to his bride or to his unborn children without interference by the law It does, however, recognize the duty to see that the remains are decently interred in the asylums for the insane, for the feebleminded, for the blind, in penitentiaries and in poorhouses, all of which derive a considerable percentage of their rapidly increasing population from the venereal diseases Illinois spends every year millions in mopping up the floor, but forgets to turn off the faucet Since the disasters wrought by syphilis, civic, economic and vital, are greater than those caused by scarlet fever in its community cost, syphilis is obviously the more important, but the public, for evident "reasons," refuses to employ against syphilis the effective measures that have long been used against scarlet fever, including compulsory notification and quarantine The proposed ordinance now in the hands of the health committee of the Chicago council carefully excludes these two features

I am convinced that the campaign for social hygiene in this country has been worth while, for it is generally conceded now to be not a new phase of religious mania, but the earnest effort of intelligent people to stem the tide of mental and physical degeneracy which is even now painfully apparent in our population Some states compel every male applicant for a marriage license to present a certificate of freedom from venereal disease and in other less progressive states like Illinois, multitudes of fathers demand the same assurance before giving up their daughters The dean of a large educational institution recently said that among 5 000 students the number acquiring venereal diseases had in five years dropped from about 18 to less than 2 per cent

No man contends that knowledge of venereal diseases will alone restrain young men from contracting them, but some of us do believe that this knowledge will reduce—indeed has already reduced—the contamination of wives and children with these infections, and that as it seems to me, should be the slogan of the entire social hygiene movement Keep the infection out of the family and out of the stock, and confine it, so far as may be, to those who voluntarily expose themselves

What Should Chicago Do for the Venereally Diseased?

Dr William A Pusey, Chicago It is a fair statement that there are in this country at least 5 per cent of syphilitics among the adult population I am not so familiar with the figures as to gonorrhea, but 20 per cent would probably be well within the figures Three methods of handling contagious diseases are (1) control of the routes of communication, (2) restraining the liberty of the infected person until the danger is past, and (3) control of the infectious disease as quickly as possible, thus rendering patients free from danger to others These methods are potentially applicable to the venereal diseases

Several methods attempt to control the diseases indirectly the inculcation of clean living, sexual restraint, high moral standards, the regulation or repression of vice, and the control of the liquor traffic These methods only scratch the surface In large measure they appeal only to the intelligent, the careful and the conscientious I confess to feeling hopeless as to the control of these venereal diseases by these indirect methods We immediately come in contact with the insistent force of the sexual appetite, against which indirect methods are in large part futile I do not minimize their importance and would not like to see a falling off in that feature of the crusade, but I believe that if we are to control venereal diseases we shall have to control them as diseases and not as moral problems In my judgment, control by isolation and quarantine is impossible in disease so widespread and contagious over so long a period

We are therefore reduced to the third method of attack Fortunately the medical profession is particularly well qualified to do this as regards venereal diseases, better as regards syphilis than any other infectious disease, and able to do a great deal in gonorrhea by controlling its infectiousness This puts us in position to act against them as public menaces, and justifies the establishment of means for taking care of these patients Medical institutions, hospitals and dispensaries are already doing it, but lack the equipment and support for effective work

The ideal condition would be to provide universal opportunity for treatment and, I would add compulsory treatment The essentials of such a crusade would be the organization of dispensaries and small hospitals for this purpose Such institutions should be well manned and equipped for diagnosis and treatment A social service and follow-up service is essential There should be also free and easy access to these dispensaries without embarrassing restrictions

Dispensaries should have evening hours so that patients may attend without sacrificing time from their work Such facilities should be free to the abject poor, but should also have provisions as to those able to pay small fees

The proposition as to the notification of venereal diseases sounds plausible in the abstract, but it is exceedingly difficult in the concrete, and in my opinion gets us nowhere It does not even give us statistics, and it is not necessary to have statistics to prove the menace and the prevalence of the venereal diseases Such statistics, as now provided for in eleven states, are notoriously unreliable and would be laughed out of any court Likewise isolation is impracticable for the 20, or even 10 or 5 per cent of the productive adult population of Chicago with venereal diseases which last so long a time

What the Chicago Health Department is Doing for the Venereally Diseased

Dr F O Tonney (Director, Municipal Laboratory), Chicago In 1910 a venereal clinic was established in the Iroquois Hospital, and the health department began to accept specimens for examination by the Wassermann reaction and for gonorrhea, collected from charity patients At present no venereal clinics are being operated by the department of health, although specimens for laboratory tests are being collected daily

The health department has always endeavored to do educational work The morals commission constitutes the chief agency of publicity and since its establishment in 1914 has collected and disseminated many valuable data The functions of the commission are to study all phases of sexual immorality and practices which tend to promote or restrict them, or which concern the physical and moral welfare of the inhabitants of the city with a view to their suppression, to study measures to rehabilitate prostitutes, to study prostitution and the venereal diseases, and take the legal action necessary to suppress houses of prostitution, to prosecute the owners keepers and inmates of such houses, to advise the prosecuting attorney and chief of police in relation to such matters, and to make reports of their findings to the mayor and the council and recommend legislation necessary to secure these objects The work of the morals commission is exemplified in their reports relating to conditions in dance halls and places of amusement While this secures publicity, it does not relate specifically to venereal diseases and does not form data for a campaign against such diseases In 1915 out of a total of 221 433 examinations by the board of health laboratory, there were 106,400 Wassermann tests and 347 for gonorrhea Although the laboratory has sufficient space, it must have more bacteriologists before free general service can be offered For treatment there are only the dispensaries of the medical schools and hospitals

The ordinance provides for report to the commissioner of health by number cases of venereal diseases by physicians and institutions having to do with such cases, giving information as to the danger of such persons to others They shall also distribute circulars of instruction for the prevention of the transmission of such diseases, and shall report such fact to the commissioner of health

Status of Chicago's Hospital and Clinical Facilities for Diagnosis and Treatment of Venereal Diseases

Dr. Oliver S Ormsby, Chicago I limit my remarks to what is being done in the treatment of syphilis in the dermatologic department of the Central Dispensary of Rush Medical College The older methods were simple, consisting of the use of mercury by mouth, by injection or by inunction, and the employment of potassium iodid, all of which methods, except the injections, could be carried out by the patient The present methods of treatment require more equipment more time and more money, but the results warrant these At the dispensary we employ salvarsan, with the proper apparatus to demonstrate the spirochete, and have a laboratory for Wassermann tests with a worker to make the tests and administer the salvarsan At present this man makes the blood tests in the morning and assists with the treatment in the afternoon Treatment is necessarily controlled by the blood and spinal fluid tests, and it is therefore necessary to have facilities for making these tests The department has had some assistance from the social service department, and later will have one worker devoting whole time to the work. The treatment is given in courses, five salvarsan injections and from twelve to twenty-four mecurial injections, controlled by the Wassermann reaction. The treatment depends on the stage of the disease. By this method the patients are kept under control better and are given a better chance to recover, and their relatives are better protected from infection. They get the same treatment as private patients. From the standpoint of public health the infectious cases are cleared up, preventing the spread of the disease. By having a social service others are protected, and associated patients are urged to take treatment. The worker also ascertains whether or not they are entitled to free treatment. Children are sometimes brought in who have been accidentally infected, and other members of the family may then be found to be infected. Those with active lesions in the mouth and other localities are soon rendered safe to go among their fellows, otherwise the danger would exist for several weeks. Contributions have enabled the dispensary to do this work, along with the efficient work of the superintendent and the cooperation of the department. Patients of the dispensary class are apt to neglect treatment. When the treatment is carried out as outlined, the patients realize the importance of regular attendance and lend their cooperation.

DISCUSSION ON SYPHILIS

DR. HUGO BETZ (Superintendent, Iroquois Emergency Hospital) Chicago: After we find cases positive there is no recourse for them whatever as to treatment. The health department at present is not able to take care of all the patients sent to them because of lack of appropriations.

DR. L. W. BREMERMAN, Chicago: The work at the Central Free Dispensary is excellent but there are many other free dispensaries in Chicago at which venereal diseases are scientifically treated, while many have meager or no proper equipment. I think the trouble with the dispensaries for the treatment of venereal diseases is that they are run at the wrong time of day. Dr. Pusey's suggestion of night clinics is excellent. One fault with the dispensaries is that patients are not properly instructed regarding the time when they are cured. Many feel that when the acute symptoms have disappeared, they are free from infection and cease coming. Another evil is the drugstore dispensary. There should be some regulation in regard to druggists' treating venereal diseases. I always endeavor to ascertain from patients how many attacks they have had before and whether they have been treated at a drugstore or by a physician, and find in a great many instances that they have had preliminary treatment from the corner druggist.

MR. JOHN E. RANSOM (Superintendent, Central Free Dispensary), Chicago: We shall never solve the problem of venereal diseases, until we have solved the problem of sexual immorality, and we will agree that that is an educational matter. Until we have trained the people in matters of self-control and in a sense of their responsibility to the community, we shall not have solved the problem. One of the great shortcomings of what we have done in the past is that *we have not cured the patients*. I have looked over the records of our institution for 1914 and 1915 with reference to cases of syphilis and gonorrhea. Those who came once constitute the largest number, those who came twice the next, and so on, until the number who came a sufficient number of times to be cured are very few indeed. This is the problem of the administration of the institution, and so far as it fails to keep patients under treatment until cured, it is failing as a medical institution.

In the Massachusetts General Hospital, in which social service work was first started, they have a worker devoting whole time to syphilis, and during the first ten months in the special clinic for the treatment of syphilis they had 2,114 patients. These made 10,326 visits, or an average of five visits to each patient. In the ten months about 10 per cent. of the patients were lost. In a city like Boston, and this is more true of Chicago, a large percentage of syphilitics are transients whom we expect to lose.

In our institution we are treating syphilis in every department. Being a layman, I am not able to say whether it should be treated in all the departments or not, but taking the parallel of tuberculosis the greatest advances have been made in special clinics, hospitals, dispensaries and sanatoriums for this one disease. I believe that when syphilis and gonorrhea are treated in the same way, we shall be doing better work than we are doing today.

DR. B. N. NOVY, Chicago: We have in Chicago six colleges, three dispensaries and many hospitals which have dispensary connections. We see 8,066 cases in these dispensaries. They all have day hours and none has night hours. Two types of patients come to the dispensaries: one is the chronic disease carrier. He comes only when he has an acute exacerbation and stays until the acute attack is past or he has no discomfort and then leaves. The other class is the temporarily unemployed class who come for treatment. They also stay until they can secure a position. Not more than 5 or 10 per cent. of patients are cured at our dispensaries for the reason that they do not come back, or do not have the time to come back. If we had night dispensaries they would be able to come until cured.

DR. ANNA E. BLOUNT, Oak Park, Ill.: We have made two mistakes: in treating effects instead of determining causes and in treating the physical side of the question as though it were a physical question instead of a psychologic, a social an economic question. When prostitution is not a trade for women we shall not have a venereal problem. I believe the reason we have so much venereal disease at present is that our girls cannot earn a decent economic independence. Without treating the social question I believe we are only tinkering with results in all these matters, particularly as to medical cure and medical prophylaxis. I think the cure when we get it will be educational, just as it was in tuberculosis.

DR. RACHELLE YARROS, Chicago: We are doing less for cases of gonorrhea, and they are equally dangerous, as syphilis. The treatment of venereal disease is an expensive luxury, and few can afford it.

MR. W. A. CLARK (Secretary, Chicago Branch American Social Hygiene Association), Chicago: The survey contemplated is yet somewhat hazy. A group connected with the City Club and other organizations are hoping we may be able to get together persons and funds with which to make such a survey. The persons interested are men interested in social questions, not medical men. We are approaching it from the standpoint of a social problem. The assistance of men who have specified knowledge of these conditions and who are trained as public health men will aid us in getting the funds necessary to make this survey.

DR. B. C. CORBUS, Chicago: We have in Chicago, I believe, twenty-seven dispensaries. The largest are the Northwestern, the Postgraduate, the Central Free Dispensary and the University of Illinois. Today I interviewed the heads of each of these clinics as to what percentage of patients they are turning out cured. One said 25 per cent. I challenged the statement. In fact, only 1 or 2 per cent. are discharged as cured. We should consider this problem under education, isolation and treatment of cases and also under clinical facilities. Few of us realize what other cities are doing. In New York they are far ahead of Chicago. In England they have the famous Lock Hospital, known throughout the world, for the treatment and care of these cases. Chicago is not doing her share.

MR. SAMUEL E. THRASHER (President, Committee of Fifteen), Chicago: I can speak of what the Committee of Fifteen is trying to do. We do not believe we can solve the problem of the social evil in a day in a city like Chicago or anywhere else. We are dealing with only one phase of this problem, and that is commercialized vice. The great cause of commercialized vice, as we see it, is threefold: (1) undeveloped mentality, 80 per cent. of women in prostitution are subnormal; (2) overdeveloped animalism on the part of men, and (3) that avarice which commercializes these two weaknesses of human nature. So long as men and women make money out of this business—and it is a large commercialized business in Chicago today—we are not going to get far in solving this problem The Committee of Fifteen aims to destroy the profitable business of prostitution If for no other reason than for the promotion of the public health, prostitution should be suppressed

Dr A. W Stillians, Chicago In the past our failure has been to convince the patient that it is necessary for him to come back We have also failed to disabuse his mind of the suspicion that if the physician wanted him to come back it was from some ulterior motive The social service worker has time to acquire the confidence of the patient and power over him Soon after the establishment of social service in the county hospital it was recognized that an evening clinic was needed, that there were many patients who could not get to the day clinics, because of their work and the danger of losing their positions At the request of Mrs Ira Couch Wood of the Illinois Training School for Nurses, an evening pay clinic for skin diseases was established Lately it has kept open two nights a week The average attendance has been seven patients an evening, and there have been forty-nine cases since June These forty-nine patients made 192 visits Only eight patients made less than five visits, seventeen made more than five A large proportion of them, of syphilis, are clinically free and Wassermann free The urologic department of the clinic has been open only a short time, but has had twelve cases, with thirty visits We make moderate charges—$1 for consultation and medicine We found that was unjust because some required expensive medicines Now we charge 50 cents for consultation and a little over the wholesale cost of the drugs For salvarsan we charge something over the wholesale cost of the drug The Wassermann reaction costs $1, and the other laboratory examinations are made free Our financial report so far is not very good because at first we treated a good many free We treated sixty-two without recompense, but this is unnecessary, in our experience There are a few who are working at a wage insufficient to take care of them and their dependents, and we are glad to treat them We got far enough in October to feel that we could pay the physicians This I believe will have much to do with making efficient service, as many young men of high caliber and ability are willing to go into the work who would not otherwise feel able to do so

Mr Arthur B Farwell, Chicago It is all right to take care of women and men diseased, but it is a great deal better to prevent them from being diseased I speak from an experience of nearly fifty years in this work, and to me, in any of these questions the greatest power is religion, second, education, third, agitation, and fourth, the law

Dr Clara P Seippel, Chicago I should like to mention what Chicago is doing for venereally diseased children Chicago has the only institution in the world, so far as I know that cares for and educates these children while under treatment What Chicago should do for these children is also a question that I think will develop along with these other problems In 1911 in connection with the general welfare exhibit, Dr Grace Meigs and I made a survey of twelve leading hospitals and dispensaries, and were amazed to learn that 1,000 little girls came there annually afflicted with vulvovaginitis This problem will have to be considered with the venereally diseased persons and it will be necessary for the state to provide for them

Dr Mary G McEwen, Chicago The General Federation of Women's Clubs is engaged in a nation-wide campaign along this line At the last meeting of the Federation in New York the only resolution endorsed by the federation was one authorizing all clubs in New York to cooperate with boards of health and other agencies to secure adequate facilities for the diagnosis and treatment of venereal diseases, and at present a nation-wide campaign is in progress asking each club to arouse interest in the subject passing out leaflets, making surveys of local conditions a follow-up program and devising ways and means to make it practical in their own community, so that in every club in the nation they will be looking toward Chicago to find what a big city should do and then they will apply it to the smaller cities

Dr Charles S Bacon, Chicago I should like to ask Dr Pusey in his closing discussion to tell us whether he thinks agencies now existing, the dispensaries now handling this work, are probably sufficient satisfactorily to meet the situation, or would it be desirable for the municipality, or the county, to undertake to establish dispensaries and institutions for the handling of this question, just as they have for the handling of the tuberculosis question?

Dr Edward A Fischkin, Chicago It was the expression in Berlin of the German National Society for the Suppression of Venereal Diseases about three years ago that neither character, religion nor anything else would eradicate human passion The only thing that is feasible is to attempt to eradicate the disease Preventive medicine has succeeded in many other fields Dr Pusey has omitted to pay attention to the possibility of curing the disease by the large army of physicians Medical armies are not cured in dispensaries but the diseases of society are taken care of by the army of physicians outside the dispensaries, and if we want to eradicate the venereal diseases the patients must have the chance to be treated by the great army of medical men The dispensaries in Chicago, as we have seen, take care of only 8 000 while according to the figures given by Dr Pusey there must be at least 50 000 afflicted We physicians who have somewhat more chance to deal with these diseases see a large number of patients who are unable to pay It will be of advantage in gaining our point if all possible agencies carry propaganda to the workingman and others to induce them to get over their disease There are larger facilities than those of the hospitals and dispensaries, there are the aid societies of the workingmen the insurance societies, that would carry propaganda to them In Berlin that was the first effort to carry propaganda These persons should not be treated as outcasts I think these agencies are of greater benefit than all the dispensaries and hospitals which the community can establish

Dr Bertha Van Hoosen Chicago I believe the establishment of more and more dispensaries will do little toward the eradication of gonorrhea If we would tell women that they have gonorrhea whether innocently or otherwise, and that it is going to destroy their sexual organs, and take it seriously and put them in a hospital and treat them in a careful, conscientious way, we would accomplish something

Dr William A Pusey Chicago In answer to Dr Bacon I do not think present hospital and dispensary facilities are nearly adequate to handle all cases but I do think that the first step in a practical way would be to improve present services and imbue them with the importance of the sanitary work they have to do I think a desirable thing to do would be to have established one hospital in the down-town district, not only for serving that district, but as an object lesson

With regard to Dr Van Hoosen's remarks, to take it seriously, I do not think that any one who talked tonight failed to consider the seriousness of gonorrhea I challenge her statement that it is necessary to take these patients into the hospital It is ideal but we are dealing with world and not with Utopia They can be handled on their feet, and we can handle the problem better practically in that way

One point Dr Bremerman brought out I would like to have drug clerks prevented from treating syphilis and gonorrhea I sympathize with Dr Blount's and Dr Yarros' ideas but I was asked to talk on a medical topic I am just as interested in seeing people happy and comfortable as they are I do not think we can wait for a social revolution before tackling venereal diseases I have a feeling of regret when the moral issue is raised Of course it is a moral issue The discussion tonight was on a disease that is mixed up with a moral question, but we are dealing with disease and it can be handled as disease, and unless so handled we shall never get anywhere We cannot control the sexual appetite We can reach a group like this, of educated people, but not the submerged tenth and they are the real menace We must handle it as a matter of disease Education and religion will reach a certain number, and I am interested in doing that to as great an extent as possible, but I am convinced that we must tackle it as a physical proposition The problem goes back to Adam The sexual appetite is not an instinct, it is one of the fundamental appetites of man, and sexual contact can be controlled only within moderate limits The sexual appetite in the intelligent, the careful, the conscientious can be controlled and restrained It is a biologic function that cannot be restrained beyond certain limits, and we have got to deal with venereal diseases as diseases I repeat that I am ready to support all efforts for the betterment of mankind and improve the moral status, but we must not forget that man is man—and I mean the woman too—and possesses fundamental instincts that cannot be gotten away from

What this organization can do is this It can make a survey I should like to see that done we can make efforts to better and increase the provisions for taking care of the venereally affected We shall secure benefit every time we establish a well equipped well manned dispensary for that purpose Dispensaries such as outlined tonight will do inestimable good They will not eradicate the disease I shall not live to see that nor will some of the younger, but in time venereal diseases can be controlled just as definitely as yellow fever The problem is simpler than that of tuberculosis, and morally it is like yellow fever and it is amenable to sanitary handling It was a pleasure to hear what Dr Ormsby is doing and Dr Stillians It is a revolution to hear about social service work being done in venereal disease

8 Study of Low Blood Pressures Not Associated with Trauma or Hemorrhage J P Simonds Chicago—p 848

1 Acidosis in Acute and Chronic Disease—From his studies Frothingham thinks it fair to conclude that the study of the hydrogen ion concentration in the urine is not reliable as an index of acidosis, that evidence of acidosis appears at times in certain diseases, while in other diseases no evidence of it is found Those diseases which showed an acidosis at times by some of these tests are diabetes, chronic nephritis, pneumonia, acute articular rheumatism and several acute febrile conditions in the miscellaneous group Cases of exophthalmic goiter epilepsy, syphilis, chronic cardiac disease, subacute nephritis lung abscess, and many in the miscellaneous group distinctly did not show any evidence of acidosis by these tests The results in the cases of primary anemia, gastric cancer, Addison's disease, and cirrhosis of the liver were not so clearly defined and in some of the tests suggested a slight acidosis It is evident from these tests that the acidosis found in diabetes is due to different causes, in part at least, from those that produce it in other conditions It also seems likely that the acidosis met with in different diseases is due to various causes, since the response to these tests varies somewhat in the different conditions Of these tests, either the estimation of the carbon dioxid tension in the alveolar air or the so-called soda tolerance test showed variation from the normal in all the cases of acidosis They also seem to be of value in detecting the degree of acidosis

3 Action of Female Remedies on Excised Intestine—The results of this work indicate that the members of the group of female remedies that act on strips of uterus exhibit practically an identical action on strips of intestine, both in manner and degree of action The other drugs of the group have no effect on either uterus or intestine This shows that they in no sense act specifically on the uterus The following depressed the intestinal strips actively in the concentrations used Jamaica dogwood, pulsatilla, unicorn root and figwort, while valerian (the oil is very depressant) and lady's-slipper are less active, and skullcap, wild yam, liferoot and false unicorn depress very slightly The following are practically devoid of action blessed thistle, cramp bark maple bark black haw passion flower, motherwort and squaw vine They have no effect on the smooth muscle of arteries in rather concentrated solutions

5 Origin and Conduction of Cardiac Impulse—Eyster and Meek found that in the dog's heart the cardiac impulse arising within the upper part of the sino auricular node, is conducted to the right auricle and to the auriculoventricular node by two separate paths The former is a diffuse path represented by the contact of the right auricle with the node The latter path is either also diffuse in nature, involving connections above below and on the intercaval borders of the node or there are numerous possible paths offering varying degrees of resistance to the passage of the impulse

6 Metabolism Study of Goiter—A study was made of the metabolism of nitrogen phosphorus sulphur, calcium and magnesium on a patient with exophthalmic goiter, with apparently a slight hypothyroidism and responding readily to treatment The study was made in five periods of five days each, including periods of thyroid and thymus treatment In the preliminary period without treatment a marked disturbance of metabolism was noted, with pronounced losses of nitrogen phosphorus and magnesium and a practical balance of calcium and sulphur Thyroid treatment markedly stimulated the metabolism of all elements determined, this stimulation continuing long after treatment was stopped Considerable retention of all elements was brought about, the maximum effect being reached sooner in the case of calcium and magnesium than in the case of nitrogen, sulphur and phosphorus The effect of thymus administration on the metabolism was less marked than that of the thyroid, but appeared to be distinct In the thymus period the retention of all elements was depressed When thymus administration ceased the rate of retention for all elements immediately increased Thus thymus treatment appeared to depress the stimulating effect of the thyroid on metabolism, which supports the view of a possible antagonistic action of these glands such as has been suggested by others on the basis of indirect evidence The administration of thyroid caused diuresis immediately Thymus treatment had the opposite effect, leading to a retention of water, with marked decrease in urine volumes on constant water ingestion The weight of the patient decreased on thyroid treatment and increased after withdrawal and on thymus administration Following thyroid treatment there was a progressive decrease in urinary indican excretion This may indicate lessened intestinal putrefaction

7 Changes in Form of Ventricular Complex—A series of cases is reported which yielded electrocardiograms showing abnormal ventricular complexes These abnormalities consist in changes in the initial portion of the complexes, the Q, R, S group and differ from those yielded by contractions caused by ectopic stimuli and from those changes which occur with bundle-branch block These observations are taken by Robinson as evidence for the belief that in cases in which the ventricular complexes constantly show certain abnormal forms, there are functional changes in the heart which prevent the normal recovery of intraventricular conduction during diastole It is shown that changes in form of the ventricular portions of the electrocardiogram may occur synchronously with functional changes in the heart, and evidence is offered for the belief that certain abnormalities in the form of the electrocardiogram indicate functional derangement of the ventricles

8 **Artificial Respiration and Low Blood Pressure**—It is suggested by Simonds that in cases of shock in man, associated with low blood pressure not due to hemorrhage, the artificial production of dyspnea or the voluntary increase of the rate and depth of respiration by the patient may lead to improvement

December 1916 XIII No 7

9 *Case of Splenectomy for Pernicious Anemia W F Smith Little Rock—p 131
10 Mental and Nervous Effect of General Disease W M McRae Little Rock—p 137

9 **Splenectomy for Pernicious Anemia**—Smith's case was one of pernicious anemia with a disseminated sclerosis which he believes to be due to the pernicious anemia The patient's mental condition was an infection exhaustion psychosis The neurology is that of a disseminated sclerosis due to an impoverished blood stream, there being an involvement of the lower motor neurons, and there would probably be found in the motor tracts of the cords sclerotic patches The patient's present mental condition seems to be normal His disposition is happy and his outlook optimistic His physical condition has improved to the extent that he is able to walk around with the aid of crutches

26 Abstracted in The Journal, May 6, 1916, p 1491

28 **Operation for Retrodisplacements of Uterus**—In the method described by Battey the round ligament is caught in a pair of forceps at a point which when drawn up seems to take up the laxity, and made taut With a needle threaded with fine linen the proximal and distal ends are stitched together This gives us a loop of the round ligament A second and third stitch one-half inch apart toward the end of the loop are introduced through both sides of the ligament and tied, the third stitch being left long With a pair of curved forceps the internal ring is entered and the peritoneal investment of the round ligament is dessected downward and the peritoneum is punctured at a point as near as possible to the first stitch in the ligament The linen stitch left long is caught in forceps and the ligament is pulled through the artificial opening With No 1 chromic catgut the ligament is sutured to the under surface of fascia of the rectus by interrupted sutures The operation is, in a measure, extraperitoneal and the author says there is no likelihood of an intestinal obstruction taking place

can be controlled only within moderate limits The sexual appetite in the intelligent, the careful, the conscientious can be controlled and restrained It is a biologic function that cannot be restrained beyond certain limits, and we have got to deal with venereal diseases as diseases I repeat that I am ready to support all efforts for the betterment of mankind and improve the moral status, but we must not forget that man is man—and I mean the woman too—and possesses fundamental instincts that cannot be gotten away from

What this organization can do is this It can make a survey I should like to see that done, we can make efforts to better and increase the provisions for taking care of the venereally affected We shall secure benefit every time we establish a well equipped, well manned dispensary for that purpose Dispensaries such as outlined tonight will do inestimable good They will not eradicate the disease I shall not live to see that, nor will some of the younger, but in time venereal diseases can be controlled just as definitely as yellow fever The problem is simpler than that of tuberculosis, and morally it is like yellow fever, and it is amenable to sanitary handling It was a pleasure to hear what Dr Ormsby is doing, and Dr Stillians It is a revolution to hear about social service work being done in venereal disease

49 **Antigenic Properties of Beta-Nucleoproteins** —The so-called beta-nucleoproteins obtained from various tissues by extracting with boiling water Wells says, possess definite antigenic properties demonstrable by the anaphylaxis reaction As there are but few known proteins that retain their antigenic capacity after boiling this observation may indicate something as to the nature of the protein complex of beta-nucleoproteins The proteins of alpha-nucleoproteins are on the contrary, very susceptible to chemical and physical changes Beta-nucleoproteins from beef pancreas, beef spleen, and pig pancreas, seem to be similar but not identical, so far as can be determined by the anaphylaxis reaction

51 **Action of Sodium Citrate, Its Decomposition in Body** —Salant and Wise found that sodium citrate disappears rapidly from the circulation after intravenous injection into cats and dogs, but this is retarded when the doses are repeated Large doses of sodium citrate when given by the mouth render the urine alkaline Only negligible quantities are sometimes found in the urine and in the blood after feeding sodium citrate The toxicity of sodium citrate when given intravenously depends on the rate of injection, the fatal dose varying between 0 4 and 1 6 gm per kilo (approximately), but about 70 mg may produce symptoms Only large amounts of citrate are toxic when ingested Large doses given subcutaneously showed cumulative action No citrate was found in the urine when doses under 0 5 gm per kilo were given intravenously The toxicity of sodium citrate depends on the rate of its oxidation in the body Sodium citrate mixed with blood in the proportion of 1 100 inhibited coagulation for four days when kept at a temperature of 10 C

52 **Kafirin, Alcohol Soluble Protein from Kafir, Andropogon Sorghum** —A new alcohol soluble protein has been isolated by Johns and Brewster from kafir seeds, which constitutes more than one-half the protein in the seed This protein has been named kafirin Kafirin resembles zein in its ultimate composition, but is different in physical properties It contains tryptophan and apparently lysin, both of which are lacking in zein An analysis of kafirin by the Van Slyke method shows quantitative differences between kafirin and zein

53 **Proteins from Jack Bean** —Two globulins canavalin and concanavalin, and an albumin of the legumelin type have been isolated by Jones and Johns from the jack bean The distribution of nitrogen in canavalin and in the albumin has been determined

54 **Proteins of Peanut, Arachis Hypogea** —Two globulins have been isolated by Johns and Jones from the peanut These have been named arachin and conarachin Arachin contains 0 4 and conarachin 1 09 per cent of sulphur Arachin gave 4 96 and conarachin 6 55 per cent of basic nitrogen, the latter being the highest percentage of basic nitrogen recorded for any seed protein From the results obtained it seems probable that peanut press cake will prove to be highly effective in supplementing food products made from cereals and other seeds whose proteins are deficient in the basic amino-acids Feeding experiments are already in progress to determine the nutritive value of combinations of peanut proteins with other proteins obtained from the more extensively used seeds

58 **Chinese Preserved Eggs—Pidan** —This paper gives the results of analysis of a kind of Chinese preserved eggs called pidan The Chinese and other Oriental people preserve eggs not necessarily to keep them unchanged, but to make various new substances—a process analogous to the production of cheese from milk The products have been little studied and the literature on the subject is therefore limited The following changes have been shown to take place during the formation of pidan from fresh ducks' eggs (1) water in large quantities has been transferred from the white to the yolk and water has been lost from the white to the outside, (2) the ash and the alkalinity of ash have increased in a way similar to that of other eggs preserved in alkali, (3) the ether extract has decreased and its acidity is high, (4) both total and lecithin phosphorus have decreased, (5) the noncoagulable nitrogen has increased and also the ammoniacal nitrogen the latter to an extraordinary degree, and the amino-nitrogen is high From these changes the conclusion is drawn that decomposition of the egg protein and of the phospholipoids has taken place The production of pidan from the fresh eggs is probably brought about through the agency of the alkali bacteria and enzymes

60 **Dietary Deficiencies of Maize Kernel** —The results of a systematic series of experiments with ground maize in which single or multiple additions of purified food substances were made are presented by the authors The proteins of the maize kernel contain all the amino-acids essentials for growth, but the proportions of certain of them are such that they are not utilizable to a high degree as the sole source of protein The maize kernel contains both the unidentified dietary factors, the fat soluble A and water soluble B The former is present in amount too small for the maintenance of growth at the maximum rate in rats, and regardless of how satisfactorily the maize kernel is supplemented in other respects failure of perfect nutrition will supervene within a few months unless some foodstuff containing the fat soluble A (butter fat, certain other fats leaves of plants etc) is supplied Maize contains an abundance of the unidentified dietary factor the water soluble B The inorganic content of the corn kernel is not of a character suitable for the promotion of growth The addition of purified protein and salts or of butter fat and salts to the maize kernel fails to induce physiologic well-being throughout the life of the animal The addition of protein and butter fat without salts forms a poorer food mixture than the pairs of additions first named

64 **Relation Between Water and Glucose of Blood** —Hiller and Mosenthal state that the water concentration of the blood in the normal individual often shows a variation of about 1 per cent during the course of a few minutes There is no assignable cause for this inconstancy Raising or lowering the sugar content of the blood does not give rise to a corresponding change in its concentration If glycemia plays a part in controlling the water content of the blood this is so slight in its effect that other factors, such as polyuria, etc, nullify its results, except in rare instances

67 **Calcium in Normal Men** —The average daily output of calcium in urine and feces varied in the cases studied by

Nelson and Williams from 0 420 to 1 016 gm Since the individuals examined were apparently in the best of health, of ages from 13 to 70 years, and furthermore, since they were all on absolutely unrestricted diets, guided solely by appetite, the results obtained represent normal values in calcium excretion From subsequent data from the same individuals covering four additional five-day periods during an interval of more than six months, these differences remained practically within the same limits The daily combined urinary and fecal excretion of calcium, on unrestricted diets, may thus be said to vary roughly from 15 to 25 per cent

68 **Calcium and Magnesium Content of Normal Urine**—The average daily output of calcium and magnesium (calculated as oxid) for five-day periods varied in the cases studied by Nelson and Burns from 0 1685 to 0 1468 gm of calcium and 0 1912 to 0 3130 of magnesium The daily output of calcium and magnesium of twenty-five apparently healthy individuals showed seventeen in which calcium was excreted in larger amounts than magnesium and eight in which magnesium predominated over calcium The largest amount of calcium (calculated as oxid) excreted in one day was 0 4875 gm, magnesium (calculated as oxid), 0 4160 gm The smallest amount of calcium was 0 0990 gm, magnesium, 0 1180 gm Either calcium or magnesium may be excreted by way of the urine in the larger amount, in the normal individual Whichever element predominates does so constantly, or very nearly so, and seems to be independent of the character of the food ingested

70 **Urea Excretion**—Urine and blood were collected simultaneously from rabbits, and the ratio

$$\frac{\text{gm of urea in one hour's urine}}{\text{gm of urea in 100 c c of blood}}$$

was determined before and after the destruction of one kidney by ligation of its ureter, while the animals were taking similar food and the same amount of water After the operation there was no decrease in this ratio as compared with the one found under similar conditions before operation, except when urea was injected The depression of the ratio after the operation when urea was injected is interpreted as indicating that the remaining kidney had less capacity for the excretion of urea than both kidneys before operation The fact that a depression of the ratio was found only when urea was injected is explained by Addis and Watanabe on the theory that the capacity of the remaining kidney was sufficient to meet ordinary demands, but showed itself defective under the strain of the additional work thrown on it by the urea injection

71 **Pancreatic Diabetes**—The results of this study suggest that the internal function of the pancreas may be closely akin to its external function, in that on the one hand (external), it provides for the complete neutralization of the acid contents of the stomach, thereby protecting the liver in its glycogenic function, and on the other (internal), it somehow preserves the proper concentration of hydrogen ions in the tissues for combustion of glucose

72 **Effect of Sodium Carbonate in Diabetes**—Murlin and Craver recommend the normal salt rather than bicarbonate of sodium and are certain it can be used intraduodenally up to 1 per cent with entire safety However if it is kept up too long there is possibility of sloughing Signs of this were seen in one case, although it was not serious The figures for blood sugar and specific gravity of the blood prove they think, conclusively, that there may be a bona fide reduction in the percentage of blood sugar by the alkali independently of any factor of dilution If this is true there is little reason to doubt that the alkali may in man as in the dog facilitate the actual oxidation of glucose Five cases were studied

80 Arsenobenzol in Syphilis G E Brown, Miles City, Mont—p 740

75 **Value of Temporary Cholecystostomy in Gastric Surgery**—McArthur claims that in those cases of stomach surgery complicated by the need of biliary fistulae, whether gastro-enterostomies with or without excision of ulcer, resections of the stomach for malignant disease, or resection of ulcer-bearing areas, he has been able to obviate serious complications by the utilization of a temporary biliary fistula made in the normal gallbladder A double purse-string suture, inverting around a small rubber tube the fundus of the gallbladder, and bringing out the same tube through the abdominal incision or through an appropriately placed stab puncture, he says, complicates the stomach surgery but little more than the making of a stab puncture through the abdominal flank for peritoneal drainage This has been done for the past two years in a majority of his gastric operations During the early postoperative hours the bile being allowed to escape externally, fails to disturb the more or less paretic stomach

76 Abstracted in The Journal, Nov 25, 1916, p 1626

77 **Actinomycosis**—The best treatment of actinomycosis in Ramstad's hands has consisted in the removal of the primary focus, and as much of the infected tissue as possible, with prolonged free drainage Internally iodids were given to the point of saturation, and of late he has given copper sulphate internally and uses a solution of it for the daily dressing of the wounds The effect of the iodids is increased by giving them intermittently

79 **Subcutaneous Administration of Fresh Human Blood**—For several years Holm has injected fresh human blood subcutaneously under various conditions and for different diseases, with apparent benefit In a case of pernicious anemia, under frequent subcutaneous administration he has seen the blood picture go from 30 per cent hemoglobin to 85 per cent, and the red blood cells rise from 1,500,000 to over 4 000,000 in the course of a few months He says that a fairly large amount of blood (4 to 8 ounces or more) may safely be injected into the subcutaneous tissues, and perfect absorption take place, if ordinary aseptic technic be employed Blood which apparently is toxic to the patient when used intravenously may be injected subcutaneously without causing any undue reaction, and with apparent benefit Holm describes the technic he has used in hemorrhage of the newborn hemorrhage of gastric ulcer, splenomyeloid leukemia and in pernicious anemia

126 **Development of Neuritis in Animals**—The experiments reported on by Gibson and Concepcion indicate that the antineuritic vitamin is present in milk in slight amounts only and that the continued feeding of either fresh milk or autoclaved milk to animals (dogs and pigs) without suitable additions to the diet induces certain beriberi symptoms, namely, degeneration of the peripheral nerves, persistent edema and aphonia There is no evidence that autoclaving the milk for two hours has in any way affected its nutritive value Not even scorbutic changes have been observed At the best the antineuritic powers of the milk are so slight that in infant feeding the diet should be extended as soon as possible The young of healthy mothers probably come into the world with a reserve supply of the vitamin substances sufficient to tide them over nutritively until the time when, under natural conditions of life, they would begin to eat other foodstuffs

130 **Study of Kidney Functional Tests**—The nephritic test meal of Hedinger-Schlayer-Mosenthal was used by Desha in thirty-six cases In general, the results have demonstrated its value in diagnosis and prognosis as found by Mosenthal The results show a general agreement with the findings from the phenolsulphonephthalein and nonprotein nitrogen determinations While the test meal gives more information than either of the other two, it does not entirely replace them *Among blood nonprotein nitrogen values higher than 40 mg* per 100 c c, there is noted an absence of relationship between the magnitude of the value and the prospective fatal determination The Greenwald modification of the Folin determination of nonprotein nitrogen was used with satisfaction

131 **Bichlorid of Mercury Poisoning**—Thorington's patient swallowed one 7½ grain mercuric chlorid tablet The stomach was immediately washed out with about 3 gallons of water through a stomach tube The first returning water showed blood Several eggs were given and were retained Shock necessitated stimulants The most interesting feature of the treatment consisted in the large amount of water drunk much of which was retained and passed through the kidneys Every twenty minutes he was given a tumblerful until the amount drunk in twenty-four hours was about 3 gallons Each day the amount of water was lessened as gastric and cardiac complications arose However for several days the patient took from two to three times as much water as he usually consumed in a day The urine, in spite of the unusual amount passed, showed considerable albumin There was severe salivation and the heart was quite irregular both as to rhythm and tone

11 *Treatment by the Nonspecialist of Ear Nose and Throat Affections (Medecine generale et oto rhino laryngologie) Got —p 254

10 **Bacillary Glandular Affections and Inherited Syphilis** —Vergely relates that among the soldiers sent to recuperate at the hospital in his charge on the seashore, there were about a hundred who came labeled *adenite bacillaire* The glands involved were in order of frequency after the neck, in the groin, axilla, peritoneum and mediastinum Some had been suppurating for months He examined teeth, eyes and ears for stigmata of inherited syphilis, and asked if there was tuberculosis in the family, whether other children had died young, and whether the patient had ever had syphilis When anything could be found to suspect syphilis he instituted very vigorous specific treatment for it The mercury was pushed almost to the limit, for a month or two, and the long rebellious glandular lesions subsided promptly He comments that the domain of syphilis is being enlarged more and more every day, and this is fortunate, as syphilis is curable Even when tuberculosis or other affections are associated with it getting the syphilis out of the way is important progress toward the cure of the whole

11 **General Medicine and Otorhinolaryngology** —Got's long communication is in response to an official request of the military authorities for information on the ear, nose and throat affections that can be treated by the nonspecialist and those that must be sent to specialist headquarters, and the time when this should be delayed no longer The address was presented at a conference of army medical men, nonspecialists

17 Telephone Device for Locating Metal Foreign Bodies in the Tissues (Le reperage immediat des projectiles de guerre) G Houzel —p 448

14 **Examination of the Abdomen and Tongue in Typhoid Group** —MacAuliffe describes in detail the findings on palpation and percussion of the abdomen throughout the course of typhoid and paratyphoid and also the aspect of the tongue, as he has recorded them during the epidemics of these diseases since the war began He says that his data supplement the description in the textbooks The tension of the abdominal walls is most pronounced in the region of the cecum from the very first, and persists longest here When perforation or hemorrhage is impending the abdominal wall stiffens Recovery cannot be counted on till the caliber of all the parts of the intestines accessible to palpation is regular once more

15 **Suspension in Treatment of Fractures** —Cattier gives an illustrated description of various devices for this purpose as he saw the method applied "avec succes et magistralement" in the American hospitals

16 **Extraperitoneal Wounds of the Colons** —Stassen and Voncken remark that the symptoms from a mere wound of the abdominal wall may be as stormy at first as from injury of viscera A grazing wound may cause contusion of the intestinal wall with an eschar, and as this drops off the mischief may be as great as from a primary injury Extraperitoneal injury of the large intestine may entail gaseous crepitation in and around the injured area, with rapid development of a fecal phlegmon If the projectile is loose in the lumen of the intestine, it may move along and give misleading shadows at intervals of only a few minutes while, left alone, the projectile may be passed in the stools within a few days They reiterate that extraperitoneal wounds of the abdomen should not be included in the statistics of other abdominal wounds, as they are in a class apart Their only gravity is from a subperitoneal phlegmon, and an early mechanical cleaning out of the region wards this off, but the symptoms may be deceptively like those of more serious injuries The disappearance of the area of dulness over the liver, regarded by many as an infallible sign of perforation of the intestine and escape of gas into the peritoneum, has lost its diagnostic value as it may occur with these extraperitoneal wounds of the colon It seems to be connected with irritation of the nerves of the peritoneum The same might be said of all the classic "abdominal signs" Only the intensity of the symptoms, the relations between them and the clinical aspect as a whole, in connection with supervision every minute of the beat and force of the pulse, enable us to distinguish between the harmless cases and those requiring a laparotomy

Presse Médicale, Paris

November 23 1916 XXIV No 65 pp 529 536

18 *Remedy for Alimentary Anaphylaxis in Man of 29 (Etude physio pathologique et therapeutique d un cas d'urticaire geante Anaphylaxie et anti anaphylaxie alimentaires) P Pagniez and P V Radot —p 529

19 Arthrotomy of the Knee through the Patella (L arthrotomie de genou par la voie transrotulienne verticale ou oblique) Bougot and de la Rue —p 532

18 **Cure of Alimentary Urticaria**—The robust man of 29 displayed a slight tendency to corpulence but had been healthy till March, 1915, when he developed suddenly a syndrome resembling Quincke s edema, the attacks of edema coming on suddenly, lasting several hours and then completely subsiding The edema was at times so extreme that the eyes were entirely closed Chronic, intense urticaria developed at the same time and persisted in variable forms, not a day without some manifestations Twice the edema affected the pharynx, and the urticaria was accompanied by pruritus The disturbances were traced to the food, to albumin from any source, animal or vegetable, but most pronounced after the former The case was studied extensively *from several points of view, and the findings are tabulated* The various methods of treating urticaria, calcium chlorid, epinephrin, autohemotherapy, etc, were given thorough trials without benefit Finally an attempt was made to combat the anaphylaxis responsible for the condition by inducing an anti-anaphylaxis according to Besredka's principle of warding off anaphylaxis in serotherapy by giving one or more small doses of the serum an hour before the main injection The patient was given an hour before the meal a small amount of the albumin of which he was to make his meal The results surpassed all expectations, the man being thus relieved at one stroke of the disturbances culminating in the urticaria, pruritus, etc The details are tabulated in full of this method of fighting fire with fire For example, if the meal is to consist of bouillon boiled beef macaroni, bread, wine and sweets, the man eats an hour beforehand 5 gm of boiled beef, 5 gm potato, and 2 gm bread Not a trace of skin trouble follows Practically the same meal taken an hour after a preliminary ingestion of 6 gm of potato alone, is followed by severe manifestations of urticaria

Further study of the case showed that it was possible to ward off the anaphylaxis with preliminary ingestion of derivatives of albuminoid substances such as ordinary peptone This answered the purpose of the desired anti-anaphylaxis, which rendered the task much more convenient for the patient It was found that under this preliminary ingestion of a sample of the food to be eaten an hour later, or taking peptone instead the blood no longer showed the typical anaphylaxis changes but behaved like normal blood, developing the leukocytosis of digestion as under physiologic conditions, instead of the reverse drop in the leukocytes during the anaphylactic crisis The latter occurs in two phases, first, the drop in arterial pressure, the inversion of the leukocyte formula, the change in coagulability, and the pruritus, secondly the skin changes which come on and persist for many hours, testifying to the intensity of the shock to the organism In conclusion it is suggested that possibly this case may have a lesson for the treatment of hay-fever and asthma by preventive anti-anaphylaxis The patient in the case reported still has his urticaria, etc, when he omits to take the preliminary dose of exactly 0 5 gm peptone or small amount of the food to form the meal, and the interval has to be exactly one hour At the same time it is evident now that the urticaria is growing less severe than it used to be

26 Extrapleural Pneumothorax with Artificial Pneumothorax Gwerder —p 1618

20 **Orthopedic Devices**—Hossly is chief of a military sanatorium caring for disabled interned prisoners of war, and he describes with twenty-six illustrations a number of apparatus that have been devised to meet the various conditions encountered and overcome the disability Diagrams are given to show the mechanical principles of a number

21 **Myelitis Under Salvarsan**—Socin's case resembles in some respects that reported by Chiari in 1913 in which a woman of 27 with secondary syphilis developed severe symptoms of cerebral irritation after three doses of neosalvarsan After four days the brain symptoms subsided but paralysis of both legs and of the bladder then developed, and the woman died in six months from general debility in consequence of suppurative bladder and kidney disease and extensive *decubitus Nothing pathologic was found in the* brain or medulla, but the spinal cord showed extensive destructive processes Socin's patient was a woman of 38 with a history of abortions and miscarriages, appendicitis at 18 articular rheumatism at 23 and pneumonia at 30 with empyema treated with resection of ribs Her husband had died of "softening of the brain" During the last six months she has been restless and agitated, with frequent headaches and some efflorescences on shoulder and knee, undoubtedly of syphilitic origin although the Wassermann test twice applied elicited no response An intravenous injection of 0 5 gm salvarsan was given, repeated five days later The first was borne well, but after the second the temperature rose and in two days there were symptoms of encephalitis These gradually subsided and symptoms developed indicating a severe and extensive affection of the spinal cord, with decubitus and a tendency to clonic and tonic spasms She died in fourteen months from debility from the profusely suppurating decubitus, etc, plus pneumonia The Wassermann test was negative throughout Socin states that there was nothing to suggest that the trouble was an acute infectious myelitis of unknown cause while the encephalitis symptoms at first sustain the assumption that the drug was responsible for the whole syndrome The stormy stage lasted six weeks and then some of the symptoms subsided, but spastic paraplegia of both legs was left and persisted till death, with sensory disturbances, all indicating myelitis of the cord in the lower cervical region affecting predominantly the lateral columns The necropsy findings are described in detail They confirmed in every respect the assumption of toxic myelitis The freedom from phenomena of degeneration in the sensory roots testifies against the trouble being due exclusively to the arsenic element Socin adds that *658 per cent of all the* fatal encephalitis cases occurred with doses of 0 5 gm and over

27 **Diabetes and the War**—Gottstein and Umber relate that all writers on diabetes have deplored the lack of reliable data as to the prevalence of diabetes The mortality records

afford little information as comparatively few die from diabetes and the existence of the diabetes is not mentioned when they succumb to an intercurrent disease The war has unexpectedly bridged this gap in our knowledge of diabetes, as, in the state regulation of the food supply, all requiring a special diet were compelled to bring a medical certificate to that effect They could thus obtain the extra fat they needed and all the diabetics took advantage of this, even the milder cases The opportunity was utilized to obtain specific data on the age, profession, etc, and duration of the diabetes The statistics thus collected in Charlottenburg, a fashionable suburb of Berlin, show that there are 706 diabetics there, of whom about 58 per cent are males In five cases both husband and wife are diabetic, in one case father and adult son This is a proportion of 2 3 1,000 inhabitants while in Berlin proper the proportion is only 1 2 or 1 3 1,000 About 33 per cent of all the cases were at the age of 60 to 70 while only 2 per cent were in the twenties and 6 8 per cent in the thirties These statistics confirm the graver prognosis the younger the age The duration of the diabetes was given as six years in fifty-three diabetics in the fifties, and over nine years for sixty-six in the sixties, including five with diabetes for over twenty years The vicissitudes of the war do not seem to have brought on diabetes in the previously healthy, and the predisposed do not inevitably develop it

28 **Bridging Gaps in Nerve**—Bethe transplants a segment of a corresponding nerve from the cadaver, and commends this method of bridging a gap as it has proved its reliability on dogs in the clinic The great endurance of excised segments of nerves permits thorough bacteriologic tests for their sterility before they are grafted Blood from the cadaver in question can also be tested for the Wassermann reaction When the segment is excised from the fresh cadaver, he cuts the peripheral end slanting, to be sure to recognize it The nerve segment is placed in a small Petri dish inside a larger one and is placed on ice, while other scraps are taken for bacteriologic tests The nineteen segments he has prepared to date, taken from seven cadavers all happened to be sterile He has thus transplanted nerves in four clinical cases All healed in place without any temperature reaction In dogs the implant heals in place in four or five days so that further immobilization is unnecessary Small stitches, only 2 mm from each end, parallel to the course of the fibers, are much better than larger stitches He uses the finest eye needles and No 000 silk Even with this care, some of the fibers may get caught in the stitches For a nerve with a diameter of 2 or 3 mm he takes six or eight stitches, applies a starch dressing and lets the animal run around By the fourth or fifth day the dressing is taken off and the animal uses the leg freely, none of the sutures ever seemed to have loosened He advises to use the corresponding nerve from the cadaver for the graft, but thinks it scarcely practicable to fit the ends of the bundles of fibers exactly like to like

29 **Epidemic of Dengue in Argentina**—Kraus states that nearly the entire population of two towns one in Argentina and one across the border in Uruguay had dengue last spring and it spread throughout that Argentine province but died out in March and April There were no complications and no fatalities, but convalescence was protracted and the patients felt extremely weak and had no appetite No micro-organism could be cultivated from the blood or detected with the microscope The leukocyte count was low in many cases, down to 2 200 leukocytes in some with increased numbers of lymphocytes and large mononuclears but no eosinophilia was evident in the convalescents The disease did not seem to be transmitted by direct contact, but it is probable that the swarms of *Culex fatigans* and *Stegomyia fasciata* exceptionally prevalent that season were responsible for the transmission He adds that dengue has been known for years in Brazil and Argentina, but this seems to be the first description of it there to be published

30 **Diagnosis of Duodenal Ulcer**—Nowaczynski reports three cases in which the clinical picture indicated abnormal conditions in the pylorus calling for operative treatment, but this diagnosis was not sustained by the operation The trouble proved to be adhesions between the stomach and liver or adhesions as far away as the spleen region, suggesting a fresh anatomic lesion and inducing spasm of the bowel These spastic conditions affect the stomach and by reflex action modify the stomach functioning This altered functioning of the stomach may be manifested by pylorospasm, hypertonus, exaggerated peristalsis and hypersecretion with its train of subjective disturbances If then are superadded on these symptoms, the disturbances from altered conditions in the vegetative nervous system, such as are common with duodenal ulcer, the diagnosis of duodenal ulcer is almost inevitable In one of the three cases described occult blood in the stools aided in misleading the diagnosis There did not seem to be any lesion elsewhere in the bowel that might have explained it It is hard to explain the source of the occult blood found constantly in the stomach content in the case in which an old healed ulcer was found in the duodenum, the blood certainly came from the stomach in this case It is a question whether local violent and painful contractions of the stomach can cause laceration of vessels enough to explain the blood findings In the three cases reported there had been stomach trouble respectively for ten weeks or twelve years, five years and one month, with intervals of freedom from symptoms The patients were 33 25 and 23 years old In the last mentioned case the disturbances began suddenly with intense pain in the stomach and bloody vomit The repeated vomiting relieved the pains but they soon returned regularly after each meal By the end of the month the pains had become stronger and continuous but there was a good appetite and no occult blood in the stools A gastric or duodenal ulcer seemed almost certain and as the pains kept up unbearable, the abdomen was opened The stomach was somewhat enlarged and the pylorus contracted, but no signs of an ulcer could be detected in stomach or duodenum In the spleen region stout adhesions were found, relics of perisplenitis A gastro-enterostomy was made with a short loop

33 **Cystic Kidney**—Karo removed the right kidney on the diagnosis of pyonephrosis but found this a mistake as it was evidently a congenital cystic kidney The other kidney was enlarged but seemed to rally to the task thrust on it The patient had immeasurably improved over his previous condition, when an intercurrent pneumonia proved fatal by the end of the month The case is reported as showing that bilateral cystic kidney will permit nephrectomy under certain circumstances

37 **Weil's Disease** —Baumler remarks that the army experiences have confirmed the peculiar restriction of this disease to the younger men and the summer months, and its prevalence at certain points in small epidemics Another feature is the frequency of cases in which swimming pools seemed to be a factor in its spread Differentiation is simple and easy now since it has been shown that intraperitoneal injection of the blood in a guinea-pig reproduces the typical disease Krummbein and Frieling have recently announced that the disease can occur in dogs and be transmitted by their bite or by fleas from them The disease is rare among civilians Baumler has encountered only one case in civilian circles in his fifty years of practice This was in 1894, and he reproduces the clinical notes on the case It was extremely severe, the prolonged fever severe nephritis and jaundice in the carpenter, 26 years old, being more pronounced than in the classic type of Weil s disease There were also urticaria, parotitis, cystitis and general hydrops and actual convalescence did not set in until after the ninth week The man then gained over 37 pounds in two months Bäumler publishes the details mainly to emphasize the complete recovery, recent examination having shown the man sound and robust with healthy children

38 **Treatment of Hemangioma** —Stromever squeezes out the contents, compressing the afferent vessels to keep out influx of more blood, and then injects alcohol, forcing it against all parts of the wall of the hemangioma He has thus treated thirty patients with hemangioma, the success was prompt and complete in all He keeps up the compression for a minute or two after the injection The procedure is repeated at intervals of one or two weeks Three or four sittings are usually required for a hemangioma as large as a walnut

44 **Five-Day Fever** —Topfer incriminates the louse in the transmission of this disease called wolhynic fever by His He mentions other features of the disease and of the short thick bacilli he found in lice that had bitten patients—all testifying to the analogy between this disease and typhus, although they are well defined separate diseases Probably the germs causing them are closely allied

58 **Biology of Body Louse** —Schaefer calls attention to the way in which body lice are liable to drop off when the clothing is being taken off They let themselves drop to seek more sheltered spots when they are thus exposed to the light and air He was examining in the open air some war prisoners who complained of being sick As one of the men stripped off some of his clothing Schaefer saw a falling louse caught up by the wind and flung against his coat It dropped to the ground from the smooth surface of the coat, but since then he never stands to leeward of a person suspected of harboring lice, and has never become infested with them, although he has had occasion to vaccinate and examine thousands all more or less louse-infested

59 **Hemolysis by Radium** —Hausmann relates experiences which show that the radium rays are able to hemolyze rabbit red corpuscles suspended in agar plates This seems to be the work of the beta rays

60 **Treatment of Bacilli Carriers** —Herz states that the central hospital for epidemic diseases in his charge has had a constant average of 700 typhoid or paratyphoid cases, and thus has provided ample opportunity for study of various epidemiologic questions, especially those connected with carriers The stools and urine were examined for bacilli day by day or on alternate days, in order to detect any possible connection between the elimination of the bacilli and clinical manifestations By this means it was ascertained that any intercurrent febrile affection seemed to check the elimination of the germs This suggested that an artificially induced rise in temperature might have the same effect To induce this, the corresponding vaccines were given a trial, but did not prove effectual Then parenteral injection of a protein was tried and this seemed to answer the desired purpose Herz selected milk as the best available protein, as R Schmidt has reported that this induces a therapeutic fever in hemophilia pernicious anemia, leukemia, etc , Muller has thus treated also inflammatory processes, bubo, phimosis and epididymitis while Saxl has been applying it systematically in typhoid Herz injected into the gluteal muscle 10 c c milk, boiled in the water bath About eight or ten hours thereafter the temperature rose, sometimes with a chill, it kept high for two or three hours and then dropped back to the previous figure No by-effects were noted except slight headache in some cases The rise in temperature was moderate, and variable in different patients and at different times in the same patient No such temperature response was obtained as is the rule in blood disease In the bacilli carriers besides the fever, it was noted that the bacilli were driven out into the blood and some were eliminated in the urine The blood picture was also modified, and there is reason to assume that any local inflammatory process was also whipped up These biologic phenomena are accompanied by mobilization of antibodies, and these various factors seem to combine to eradicate the lurking bacilli in the body and put an end to the "carriership" Of course time alone will show whether the parenteral protein treatment gives durable results To date, the stool and urine findings have been constantly negative in four chronic cases given four or five injections In the recent cases one injection sufficed He emphasizes the importance of this from a military point of view, as otherwise these men would have to be kept for weeks or months in the hospital after complete clinical recovery, encumbering the hospitals and depriving the army of their services On the other hand, the reaction to the parenteral protein is comparatively insignificant, the disturbances being less, as a rule than even those from antityphoid vaccination

67 **Systematic Study of the Blood Picture in Pulmonary Tuberculosis** —Turban has found the accompanying chart extremely useful in recording the blood findings over long periods for comparison In protracted chronic cases, once a month is the routine interval, avoiding the menstrual period

in women and the few days before and after it unless its influence on the blood picture is being studied in particular Daily records of the differential blood count over long periods might afford very valuable information, it requires extreme care and practice in enumerating the nuclei as otherwise comparison between the findings of different observers is unreliable

68 **Accumulation of Medicinal Agent in Tuberculous Tissue** —Stern thinks that the principle of chemotherapy, in the sense of a special affinity of the bacilli or of the diseased tissues for the introduced drug, has not been proved But there is every reason to assume that where the circulation is especially active the drug is brought into the region, then by checking the circulation, the drug can be kept there It is possible to influence artificially the circulation along these lines Among the arguments he presents to sustain this view of the lack of a firm scientific basis for the so-called chemotherapy is the efficacy of potassium iodid in sporotrichosis Nothing else ensures so prompt and so complete a cure as this, but potassium iodid does not act on the parasite, there is no "affinity' between them It disintegrates the cells of the infiltrate, leaving the parasites unmodified This is its action also in syphilitic gummas, it breaks up the pathologic tissue cells but does not destroy the spirochetes No one claims that it kills the spirochetes We are far from the realization of an effectual chemotherapy for tuberculosis, but in the meanwhile we are able to draw and hold the drug in the diseased area by various measures to induce hyperemia in general and also local hyperemia Attempts to increase the action of phototherapy by salve treatment and efforts in the line of accumulating deposits of the drug in the pathologic area by stasis or other hyperemia—thus storing up potassium iodid for instance, in the diseased tissues—deserve the greatest attention and imitation Here is a field, he adds, in which actual experience takes precedence of theorizing

70 **Connection Between Trauma and Tuberculosis** —Orth has had occasion to testify in four additional cases in which the accident insurance companies were questioning the connection between a trauma and following tuberculous disease or aggravation The details of these (ninth to twelfth) cases are given in full In three of the cases he testified to the effect that the trauma had no direct connection with the tuberculosis, but, in the fourth case, that there could be no doubt that the trauma had been responsible for the fatal hemoptysis that had followed

Zentralblatt fur innere Medizin, Leipzig

October 28 1916 XXVII No 43 pp 753 768

73 *Alimentary Dropsy (Ueber Hungerodeme) A. V Knack —p 753

73 **Alimentary Dropsy** —Knack describes what he calls *Hungerödeme* as it has been observed in various devastated regions and prison camps during the war It resembles the edema with kidney disease but comes on with dysenteriform symptoms The extreme edema in certain parts of the body and the motor feebleness are the main features Analysis of the various epidemics demonstrates apparently some connection with the food, not so much quantitative as qualitative The persons that suffer from this hunger edema are not so much the ordinary poorer classes as those reduced to penury by the war or other cause The bad quality of the food, spoiled potatoes, etc, induce a primary severe upset in the digestive organs and this entails the cachexia, edema and other features of the syndrome in question It has never been produced experimentally under starvation alone

75 *Case of Bilateral Mammary Tuberculosis P Gilberti —p 321
76 **Catheterization of the Ureters* (Contributo allo studio del valore del cateterismo ureterale) E Pirondini —p 331

75 **Bilateral Mammary Tuberculosis** —Gilberti's patient was an unmarried woman of 50 and there was no evidence of tuberculosis elsewhere than in the left breast The lesion had been developing for seven months and was as large as a hen's egg He resected the entire breast and the otherwise healthy woman rapidly recovered She returned a year later with a similar tumor in the right breast It had been noted for two months, and he removed this breast also Scanty tubercle bacilli and the characteristic tissue findings were demonstrated in each of the lesions This isolated bilateral tuberculosis of the breast is very rare, still more so the development in a virgin

76 **Catheterization of the Ureters** —*Pirondini* concludes this long study of the advantages and the drawbacks of catheterization of both ureters, with the statement that nothing else can compare with it in reliability, but that even this may prove misleading The catheters may injure the tissues and falsify the deductions, or the patient's general condition may interfere with instructive findings An exploratory incision, exposing the kidney, may usefully supplement catheterization of the ureters in dubious cases He adds that massage of the kidney as a means to induce unilateral polyuria is futile His wide experience with catheterization of the ureters is reviewed with much detail

Siglo Medico, Madrid

November 18 1916 LXIII No 3284 pp 737 752

77 **Experimental Arthritis in Rabbits* (La artritis experimental en los conejos contribucion a la patogenia de la artritis en el reumatismo febril) H K Faber —p 738
78 *Simultaneous Spastic Spinal Paralysis of Alimentary Origin in Two Brothers (Doble caso de latirismo) E F Sanz —p 741

77 **Experimental Arthritis and Pathogeny of Arthritis in Rheumatic Fever** —This is a translation of Faber's report which was reviewed in The Journal, 1915, lxv, 1850

78 **Spastic Spinal Paralysis of Alimentary Origin** —Two brothers 27 and 19 years old, previously healthy and of a healthy family boarded for three months together at a place where dishes made with the chick-pea formed a large proportion of the food By the end of the third month both brothers noted that it was increasingly hard for them to move their legs and in a few days they could not walk or stand without aid, while there were spasmodic contractions at times The older brother was able to get about with a cane, but the younger was entirely helpless The syndrome is that typical of spastic spinal paraplegia in both, and it has persisted unmodified during the eight months to date, without any other symptoms, all the disturbances being limited to the lower limbs The only probable explanation for the trouble is poisoning from the flour made from the seeds of the chick-pea the vetch of the lathyrus species, which is known to be capable of inducing bromatologic intoxication or lathyrism It is not so rare in Spain, Sanz remarks, as the paucity of the literature on the subject would indicate The two brothers in question were farm hands free from venereal disease and abuse of alcohol He relates that the plant in question is the *Lathyrus cicera* or *clymenum* which is called *guija* or

almorta in Spanish, *Platterbse* in German, *gesse* in French, *cicerchia* in Italian and *chich* or *chick-pea* in English The poisoning is probably not so much from the seeds themselves as from some special modification of them from still unknown causes Rost has published a statement to the effect that poisoning from this source is more common in rainy than in dry seasons No attempts to reproduce lathyrism experimentally in animals have proved successful to date, and no necropsy reports of clinical cases have been published, to Sanz' knowledge

Brazil-Medico, Rio de Janeiro

October 28 1916 XXX No 44 pp 345 352

79 *Gonorrhea in the Male at Rio (Sobre o tratamento da blenorrhagia do homem no Rio de Janeiro) A Pereira —p 346

November 4 No 45 pp 353 360

80 Pigeon Proteus and Its Transmission (Pesquisas sobre o ' Hemo proteus columbae) H de B Aragão —p 353

81 Chloroform for General Anesthesia and Its Dangers (Annotaçoes praticas sobre a chloroformisação e seus perigos) O Clark —p 354 Commenced in No 43 p 337

79 **Treatment of Gonorrhea in Males**—Pereira has been impressed with the frequency of pyelitis in gonorrhea at Rio It seems to be a part of the normal evolution of gonorrhea in the male there He says that it can occur only by the infection being carried to the kidney pelvis by the blood or lymph, and this confirms the assumption that gonorrhea is not a local but a general affection This explains why local measures fail to prevent its passing into a chronic phase He has been impressed also with the way in which the gonorrhea seemed to be permanently cured when the man had contracted syphilis likewise and was being given treatment for the latter Under salvarsan alone it showed no improvement, but under a specific course of mercury the gonorrhea seemed to be aborted The conclusion is inevitable that a general course of mercurial treatment is indicated in gonorrhea After extensive experiments he decided that mercury biniodid seems the best adapted for the purpose The dosage need not be so large as for syphilis He has thus eradicated the gonorrhea in from twenty to sixty days with ten to thirty-six injections of 5 mg or half this, of mercury biniodid (*bi-iodureto de mercurio*), repeated daily or on alternate days, without any local measures By way of the stomach, the action is slow and inconstant, and intramuscular injections are less effectual than intravenous In conclusion, Pereira reiterates that chronic urethritis is almost incurable at Rio by the other treatments advocated to date, but the prospects are bright for the permanent cure without local measures, under a systematic course of mercurial intravenous injections

85 *The Hand Sign of Syphilis (El signo de la mano Contribucion al diagnostico de la sifilis) J N Posadas —p 305

86 *Biologic Diagnosis of Pregnancy F A Deluca —p 307

87 *Occlusion of the Urethra in Treatment of Gonorrhea H Dasso —p 309

88 Climatotherapy of Tuberculosis in Argentina J M Escalier and P D Galli —p 317

85 **The Hand Sign in Syphilis**—Posadas for the last three years has been noticing very often in his syphilitic patients, with or without treatment, a pinkish spot in the hypothenar region or palm There is evidently a special dilatation of the capillaries in the skin of this region on both hands It forms a triangle with the base line running from the middle of the inner half of the first fold on flexing the root of the hand to the middle of the ulnar edge of the hand The inner side of the triangle runs from the middle of the ulnar edge of the hand to the digitopalmar fold corresponding to the little finger The triangle thus occupies the hypothenar region but there may be merely a round spot instead of a triangle The skin may look pinkish or resemble a scarlatinal eruption or even a vascular nevus, but the redness never extended beyond the outline of the triangle described above He found this hand sign in 321 of 493 syphilitics examined, that is, in over 65 per cent. but never earlier than the third year after infection Omitting the patients with infection of more recent date, he found this sign pronounced in nearly 81 per cent of 397 patients Specific treatment renders it more intense for the time being and then it returns to its former aspect

86 **Biologic Diagnosis of Pregnancy**—In this preliminary communication Deluca calls attention to what he calls the urine-hemolytic reaction as a sign of pregnancy Tests with sheep red corpuscles, rabbit hemolytic amboceptor and guinea-pig complement showed that addition of urine from a pregnant woman hastened hemolysis by five or ten minutes Urine from men and from nonpregnant women had the opposite effect, retarding hemolysis The pregnant urine lakes the red corpuscles even without the hemolytic amboceptor, but it took several hours for this The presence of complement is indispensable The findings were constant in the thirty pregnant women examined, in the second to the ninth month of the pregnancy In one woman the hemolytic reaction was pronounced although six weeks had passed since an abortion at two months

87 **Occlusion of the Urethra in Treatment of Gonorrhea**—Dasso is convinced that keeping the tissues laved with the medicinal substance is an important aid in treatment, and hence he applies a rubber covered clamp to close up the urethra in treating gonorrhea It can be applied and removed as often as necessary the aim being to maintain the local medication day and night

89 *New Bladder Made from Rectum in Treatment of Exstrophy (En ny Metode til Helbredelse af Ektopia vesicae) T Rovsing —p 1109

89 **Treatment of Exstrophy of the Bladder**—Rovsing gives an illustrated description of two methods for remedying this condition The second is only to be applied in case the first proves unsatisfactory The first method is merely to introduce a retention catheter and suture the bladder walls around it With the second method the trigonum is implanted in the rectum which is severed at the sigmoid flexure and drawn forward to make the new bladder In the case described in detail he thus produced a closed and continent bladder, which contracts and can be voided voluntarily and with normal frequency, but the patient is left with a fecal fistula above, where the stump of the sigmoid flexure is brought out Rovsing regards the discomfort from a well made fecal fistula in sound tissues as less annoying than that from exstrophy of the bladder With his first method the peritoneum is not opened The bladder is separated from the urethra and the latter is sutured separately while the retention catheter assumes its functions The bladder wall loosened up on all sides is sutured around the catheter This method has proved satisfactory in a number of cases, the bladder increasing in size to almost normal capacity in time In case the bladder is too irritable for this, a urinal is worn This method is far from ideal, but in the most harmless manner it does away with incontinence, seeping of urine and all its evils When the bladder does not permit this technic the only choice is between transplanting the ureters into the skin or into the bowel Each has so many drawbacks that he prefers what he calls his second method, cutting away the bladder walls except around the trigonum and bringing the rectum over to make a new bladder This method was successfully applied to a boy of 3 after the first method had been tried and failed, owing to conditions left by bilateral herniotomy

THE PATHOLOGY AND PATHOGENESIS OF ECZEMA AND DERMATITIS

THE IDENTITY OF THE TWO DISEASES *

WALTER JAMES HEIMANN, M D
NEW YORK

With a tenacity for tradition positively British, and an ancestry worship almost Chinese, dermatologists have clung to the views of their revered dead and to obsolete designations, less with wisdom than with a certain commendable if sentimental loyalty The term eczema is derived from the Greek, meaning to boil up, to bubble Actually, the picture of bubbling is suggested as much and as little by eczema as by herpes, pemphigus, or any other vesicular or bullous disease Thus, even as a simile the designation is defective This in itself would be a matter of minor import, did not the term lead us astray with reference to a closely related or indeed actually identical disease, simple dermatitis It is the object of the present paper to illustrate this identity, and to suggest the abandonment of the word eczema, or at least to restrict its use to a precise group of cutaneous manifestations In a measure the disadvantages of a purely figurative appellation will be counteracted as its limitations are realized and its limits defined If the term eczema survives, it will do so in the sense in which Norman Walker regards it, as a dermatitis of the cause or nature of which the observer is ignorant It will then indicate a diminishing group from which, little by little, as our knowledge grows, the component elements will be transferred to the ever increasing body of dermatitides of known origin

It would be more rational to eliminate the term entirely, and to speak of dermatitis of known etiology on the one hand, and of unknown etiology on the other, the latter corresponding to what has hitherto been called eczema It might of course be permissible to speak of eczema of known and unknown origin, with the understanding that eczema is a dermatitis The objection to this resides in the fact that there is no sound reason for the existence of an inexact word when an exact one may be substituted The poet's famous query as to the value of a name may in general be a thrust well aimed, but in science it is not, and concerning the subject at hand the misnomer is vicious, because it implies invalid and indefensible distinctions

A description of the clinical features of eczema, since these are well known, may be dispensed with, save in so far as from time to time such adversions may be required in order to maintain the thread of discussion By eczema shall be understood what is commonly included under this caption in any representative textbook on dermatology By simple dermatitis shall be meant those forms of cutaneous catarrh represented by various types of dermatitis venenata, occuptional dermatitis and the like Both groups are characterized by itching or burning and by more or less extensive erythematous eruptions, associated with papules, vesicles, pustules, weeping, crusting, scaling and lichenification The combination of these lesions, their extent, the course of the disease, all depend in part on the nature of its pathogenic agent or agents, and in part on the degree and duration of their activity

It is certain that objectively eczema and simple dermatitis are indistinguishable The sites affected, the polymorphous character, the nature of the primary and consecutive lesions, the manner of involution with crusting and scaling, or scaling alone, the subjective symptoms, all are alike in both Wherefore it appears unreasonable to separate them clinically An apparent point of departure is reached anamnestically, however, in that a known cause is ascertainable in dermatitis, but not necessarily in eczema Closer scrutiny, nevertheless, reveals that in the former, although the cause is recognizable, it is pathogenic only in selected individuals so that it at once becomes obvious that the operation of the external agent alone is incapable of provoking the morbid process Furthermore, a discriminating analysis of cases of eczema so frequently discloses the presence of a probable local excitant, that in those cases in which one seems lacking, the want must be ascribed less to its actual absence than to limitations of the patient's or physician's power of observation which prevent its discovery

Microscopically, the two conditions are alike, as will appear below Therapy throws a certain, though perhaps less conclusive, light on the identity of the two processes The milder cases of both respond to similar local therapy The severer cases require the same local as well as general measures for a cure to be effected In thus broadly surveying the field, then, two conditions are under inspection which are clinically and histologically identical, the pathogenesis of which follows in the same channels, and the treatment of which is successful only when conducted along the same lines It is absurd to continue to separate two conditions which in every respect correspond to each other, and to the support of their absolute identification the ensuing will be dedicated

HISTOPATHOLOGY

Unna[1] divides eczema into two phases, a vesicular and chronic or true form The vesicles are single chambered, variable in size, contain three parts of serum and fibrin to one of pus cells, and lie in the malpighian layer Pressure exerted by the vesicles causes flattening of the surrounding rete cells As the epidermis grows upward the vesicles rise, finally reaching the corneous layer, which consists of nucleated cells The rete pegs are enlarged in all diameters but their general shape is not materially altered In the papillae and pars reticularis a dilatation of the vessels takes place, the endothelium of which is swollen, while a perivascular infiltration of lymphoid cells is present

Chronic eczema exhibits three distinct epidermal features, parakeratosis, acanthosis and spongiosis The first is an expression of incomplete keratinization, which is evidenced by persistence of the nuclei in the stratum corneum, the second is due partly to proliferation of the cells in the rete and pegs, and to interstitial edema, while the last, spongiosis, is entirely due to interstitial edema Spongiosis imparts a curious aspect to the rete The intercellular spaces are broadened by accumulated fluid, forming a tracery of canals which simulates the arrangement seen in a transected sponge This phenomenon is at the bottom of chronic vesiculation, as will presently appear In turn, the vesiculation and spongiosis itself cause crust or scale formation Ivan Bloch[2] emphasizes a productive inflammation in the cutis, persistent vascular dilatation with engorgement and surrounding lymphoid cell deposits Pautrier[3] divides the contents of vesicles into an uppermost layer consisting of serum, a second of serum and leukocytes, and a third of leukocytes These three again constitute the roof of the vesicle, leaving a space below twice as broad, filled with pus and degenerated epithelial cells For the rest, Pautrier, as well as other authors, notably Darier,[4] Ehrmann and Fick,[5] and Walker[6] agree with Unna

The varieties of eczema, such as the erythematous, papular, vesicular, weeping, crusted and scaling, will be described shortly Verrucous eczema depends on excessive acanthosis, lichenified and elephantiasic depend on the degree of productive inflammation and lymphatic engorgement, respectively, present in the cutis These types are incidental rather than basic and their detailed elaboration would add nothing to the present paper

In my own studies I have been able to confirm the foregoing The formation of the vesicle of acute eczema is different from that of the chronic type In the former an intracellular or parenchymatous edema in the rete is the starting point Accumulation of fluid in the cytoplasm causes the cells to enlarge and become round, while the nucleus is pushed toward the periphery of what is now a sac of fluid Microscopically, such a cell resembles a cavity This process is known as *alteration cavitaire,* the designation having been suggested by Leloir In chronic eczema the vesicle depends on interstitial edema The saturation of the intercellular spaces stretches the epithelial threads to the breaking point, freeing the cells which then become spherical Thus, whether the edema begins within or without the cells, the latter finally become rounded out When numerous contiguous cells are so altered they lie in a space, the vesicle proper, and are surrounded by serum, fibrin and migrated leukocytes, chiefly of the polymorphonuclear variety The rounded epithelial cells resemble toy balloons, an observation which caused Unna to call the process ballooning degeneration The wall of the vesicle is formed of contiguous epidermal elements flattened by the pressure of the vesicle contents Although the vesicles are always single chambered, they are often numerous, and when separated by thin walls may simulate multilocularity Usually in acute eczema and invariably in chronic, spongiosis, acanthosis and parakeratosis, as affirmed by Unna, are present

Erythema is due, in both the acute and chronic stages, to dilated vessels, papules, to edema of the papillae, infiltration therein, hyperplasia of collagen, or all three, and scaling to parakeratosis In the acute form weeping is almost invariably due to the rupture of vesicles, while in the chronic it may be due to this, but is more frequently occasioned by the interstitial edema The frail and imperfectly keratinized corneous stratum is washed away by the saturation of the epidermis, thus exposing the rete, out of which wells up the excess of serum From whatever source, the fluid dries and forms crusts, additional elements of which are bacteria, leukocytes, exfoliated corneous and degenerated rete cells and erythrocytes Should the vesicles have become purulent, the crusts assume the characteristics of dried pus

SIMPLE DERMATITIS

Very little attention has been devoted in the literature to the microscopic study of simple dermatitis Kulisch[7] produced vesicles experimentally with croton oil and cantharides, duplicating Hebra's classic investigations, which had caused the latter to conclude that eczema was always of external origin It would be redundant to paraphrase Kulisch's account of his results, as they absolutely correspond to a description of eczema More recently Weidenfeld,[8] working along similar lines, corroborated the above findings

In each of the three instances just cited the investigators were working on the problem of eczema, and had no thought of dermatitis, but it is obvious that they made no distinction between the two processes, for they produced what they called eczema by the use of external agents The latter were poorly selected, since they are vesicants and produce blisters on practically all skins Microscopically, however, the lesions were those of acute eczema

It has been my good fortune to examine specimens of skin excised from patients suffering with various forms of acute and chronic dermatitis due to chemical agents vocationally employed They were identical in their minute anatomy to eczema in its various forms

RESUME

Microscopically, then, eczema and simple dermatitis are one and the same process In terms of general pathology they represent, as the case may be, acute, subacute, or chronic catarrhal inflammation As Johnston[9] says "Eczema differs not at all from the other fibrinous lymphocytic inflammations except in the histologic peculiarities occasioned by its site" A belief is nurtured in some quarters that dermatitis begins with epidermal changes, those in the cutis being secondary, while the reverse obtains in eczema Weidenfeld's studies, however, adequately disprove this Furthermore, such reasoning is fanciful, for all inflammatory processes, by their very nature, depend on vascular changes, and it is impossible to distinguish microscopically, when alterations have occurred both in the epiderm and corium, which preceded and which followed

PATHOGENESIS OF ECZEMA

There are three possible ways by which the pathogenesis of eczema may be explained through internal causes, external causes, and the activity of outside agents in predisposed individuals

Internal Causes In the earliest French literature eczema was considered a dartre After the concept had been discarded by Willan[10] as meaningless, Hardy[11] reapplied it clothed out as the "dartrous diathesis" A dartre was a vice or poison capable of protean manifestations, one of which was eczema In modern France this idea has been perpetuated as arthritism, in England as the gouty diathesis Besnier[12] elaborately included among the internal causes of the disease five groups

1 Predisposing heredity, syphilitic and alcoholic ancestors, ancestors who suffered with other skin diseases, constitutional weakness, diabetes, lithiasis, bronchitis, etc
2 Physiologic dentition, pregnancy, lactation
3 Nervous
4 Functional digestive, assimilatory and excretory disturbances
5 Local predisposing ichthyosis, keratosis pilaris, seborrhea, skin folds and body orifices

One and all of these excitants has had its champions Three of the list, however, deserve emphasis, the nervous, digestive and metabolic causes A varied fabric of fantasy has been woven about the role played by the nerves in producing eczema, and yet undoubtedly a connection exists This may not be direct and probably is not, but there can be no doubt that indirectly, through its effect on body function, what is popularly known as nervousness may disturb metabolism sufficiently to provoke cutaneous diseases It will save space to quote in toto a passage from another paper[13] on this theme

> Tilbury Fox finds the disease due to "perverted innervation" Anderson mentions mental excitement, grief, overstudy, and sedentary habits among the causes, Malcolm Morris, mental depression and nervous shock, a point of view acceptable to Johnston, who denies, however, that there are any demonstrable nerve lesions Bulkley enumerates neurasthenia, nervous and mental shock, reflex internal neuroses, such as those due to dentition, and reflex external neuroses, such as scratching and irritation, as well as structural and functional neuroses

That digestive disturbances are prominent in producing eczema, as the entire literature of the infantile form of the disease illustrates, is beyond question Such causation, numerous authors agree, is not restricted to babyhood, however, and constipation is widely regarded as intimately associated with eczema, if not actually provocative thereof, the two conditions possibly being expressions of the same underlying cause

More important than the preceding is the influence of metabolism Johnston[9] asserts that "all eczemas must have a basis of failure of metabolism for their development" He alludes especially to ductless gland disturbances, and those of nitrogen chemistry Neisser[14] includes among probable causes chemical substances elaborated in the cachexias, diabetes, and gout, while Tilbury Fox[15] adds nephritis to this list Towle and Talbot[16] find disturbances of sugar and fat metabolism in infantile eczema More recently White,[17] by a series of percutaneous tests, has demonstrated that many adults with eczema are allergic to egg albumin, fat free, milk and oatmeal water, and that in a certain number of cases lactose and salt-free butter may be at fault A considerable proportion of these cases suggest that sensitization to given proteins is responsible for some forms of the disease

External Causes There are three groups of alleged external causes, local predisponants, irritants and micro-organisms Besnier[12] includes among local predisposing faults, as already mentioned, ichthyosis, keratosis pilaris, hyperhidrosis, seborrhea, and skin folds Brocq[18] regards dyshidrosis as a most frequent offender, while Jadassohn[19] actually considers it as a form of eczema itself Great unanimity is displayed among authorities as to the pathogenic function of this group Little need be said concerning local irritants, since their action is obvious They are mechanical, physiologic and chemical, as friction, pressure of implements, actinic rays, drugs, cosmetics, dyes, chemicals, such as cleansing powders, disinfectants, and substances employed in art, science and manufacture Artificial dermatitis, occupational and professional eczemas are examples of the conditions they provoke

As to micro-organisms, Unna[20] attempted to prove the existence of a special eczematogenic bacterium called the morococcus A perusal of the Transactions of the Fourth International Dermatological Congress will show how vainly he contested and how completely he was vanquished The organism he sponsored was generally regarded as the white skin staphylococcus Possibly the presence of micro-organisms in the lesions intensifies the process, or perhaps their toxins do, but their specific pathogenicity has been disproved

The Combined Internal and External Causes Willan,[10] Neisser[14] and Rayer[21] regard eczema as due to external agents operating in the predisposed Fox[15] and Fordyce[22] apply this principle to eczemas caused by chemicals, and Hall[23] and Jacquet and Jourdanet[24] to those arising occupationally

THE PATHOGENESIS OF SIMPLE DERMATITIS

This division is purely artificial, but temporarily may be allowed, partly for the sake of clearness, but more especially because it indicates how purely arbitrary is a separation of eczema from dermatitis Everything already stated in connection with eczema due to external causation and combined external and internal origin applies equally to dermatitis

THE PATHOGENESIS OF ECZEMA AND DERMATITIS AS A WHOLE

It is overwhelming, when first confronted with the task, to find a way in which to bring into accord so many causes capable of producing a relatively consistent clinical picture The difficulty, though, lies not in the number of the causes, but in the fundamental misconception that eczema is a disease It is rather, like coryza, bronchitis or nephritis, for example, an expression of disease In order to comprehend this fact we need only recall the doctrine of cutaneous reactions, of which urticaria is a simple example Innumerable causes provoke hives, but their clinical picture always remains constant After all there are not a great many manners in which it is possible for the skin to respond to disease-producing agents and one of these is the catarrhal inflammation Thus eczema and dermatitis are in effect a generic reaction to a wide variety of excitants, an index, as it were, of morbidity Bazin in 1866, according to Brocq,[18] said that eczema is a "special reaction of the skin to diverse causes" To realize this is to possess the key to the solution of the entire problem

The internal causes of eczema, disturbances of digestion, of the nerves, of metabolism, of the endocrinous glands, anaphylaxis, have been mentioned Not every one, however, in whom such conditions exist gets eczema Thus, an external factor must be sought, a local excitant to precipitate the attack It is, as a matter of fact, at times impossible to find either a general or local reason for the skin changes This is no argument that there is none, but simply an indication of inability to demonstrate it If there were actually no cause for the eruption, if the patient were in perfect health, it would necessarily follow that pathologic changes might exist without disease, a manifest absurdity

Eczema of external origin is due, as has already been outlined, to all sorts of mechanical, physical or chemical agents But if these alone sufficed to produce cutaneous alterations every one on earth would be always afflicted The truth is that they are harmful to very few individuals exposed to their action This establishes beyond doubt the fact of predisposition Such a predisposition may be general or local The first would at once identify eczema of external origin with that of internal, with the added feature of a known exciting cause The second requires somewhat further elaboration, for local predisponants, skin anomalies, as ichthyosis, secretory disturbances, as hyperhidrosis, inflammations, as seborrhea, may act as precipitating causes in connection with general disturbances, or as predisposing causes in connection with external agents In other words, local predisposing conditions are capable of playing a double role

Dermatitis of external origin can also develop only in the predisposed, or it would be universal Since simple dermatitis and eczema of external causation are alike clinically and histologically, since both are cutaneous catarrhs, and since in both the pathogenic mechanism is the same, it must be admitted that the two conditions are identical It has also been shown that eczemas of internal and external causation differ from each other in only one essential respect, namely, the absence in the former of a demonstrable precipitating cause This can scarcely be sufficient to establish eczema as a separate entity, for the quantity is mined and undetermined, and as methods of investigation are improved the former will increase at the unknown solely because it has not yet been found It simply represents the difference between the deter-expense of the latter until the latter reaches the vanishing point Thereupon eczema will automatically cease to exist

This view has already been implied in the literature Willan and Bateman,[10] Biett, Cazenave and Schedel[25] hold that there is no difference between eczema and dermatitis Fordyce[22] says that the two are clinically and microscopically indistinguishable Ormsby[26] is able to differentiate them only by the history, and not by their appearance Pusey in his textbook boldly asserts the absurdity of attempting any such distinction, and because of the splendid force of his expression and his compelling logic, the entire passage in question is worth transcribing from his work

> Hebra first cleared the subject of eczema of some of its vagueness, and also opened the discussion as to its proper definition, by declaring that eczema is dermatitis, such as can be excited in any skin by external irritants And most authors agree, or at least admit incidentally in their descriptions of eczema that its eruption is indistinguishable from dermatitis, for example, Stelwagon says, "Inflammation of the skin of artificial origin is often similar in symptomatology to that of eczema and may, indeed, be considered identical" But many authorities are not willing to rest with this They insist that it differs from an ordinary dermatitis of external origin by certain added factors, usually factors of personal equation in the patient The position of Malcolm Morris may be cited as an example of the point of view of those who hold that eczema is something more than a dermatitis Morris, than whom no one is better able to state a case, gives the following definition of eczema "Eczema is a catarrhal inflammation of the skin originating without visible external irritation and characterized in some stage of its evolution by serous exudation The definition of eczema here given excludes all forms of inflammation of the skin caused by chemical or mechanical irritants The artificial dermatitis set up by such agents is *identical automatically with the eczematous process* and gives rise to *lesions indistinguishable from those of eczema*, but it is not eczema" This seems to me a reductio ad absurdum It amounts to saying that two things which are the same are different because they are produced differently The most that this statement can mean is that there is dermatitis of external origin and dermatitis of other origin which are indistinguishable, and that he would confine the conception of eczema to the dermatitis of other origin Morris goes on "It is evident, therefore, that there is something more in eczema than inflammation of the skin due to a local and transient cause There is an unknown quantity beyond this, a pathological x which may be either some invisible source of irritation or some constitutional peculiarity or both of these factors These identical words could be used in favor of the position that pneumonia and tuberculosis are not essentially due to the pneumococcus and the tubercle bacilli respectively Indeed, in the old days this line of argument was used to prove that tuberculosis was a "constitutional" disease If it were not for this pathological x some factor of lowered resistance, we would all have pneumonia all the time, and who of us would escape tuberculosis? Further, his qualification that the process originates without *visible* external irritation is also certainly an unessential condition It makes

---

[25] Biett Cazenave and Schedel Abrége pratique des maladies de la peau, 1838 p 90

[26] Ormsby Diseases of the Skin 1915 p 187

no difference in the essential character of a dermatitis that the irritant happens in some cases to be discoverable and in others not

Leaving out these unessential qualifications, we cannot avoid the position that eczema is dermatitis, and, as far as the lesions in the skin are concerned, this statement represents the fact

Support of this attitude may be found in clinical experience In an analysis of fourteen closely observed cases (Heimann[13]) the following facts stood out An ascertainable local irritant was present in eleven, a presumable one in another case These irritants were hair dyes, scalp lotions, resorcin, or other chemicals Local predisposing causes could be determined in seven, seborrhea having been the most frequent It might be maintained that because of their relation to an external irritant, such as a hair dye, these cases were not eczema, but simple dermatitis, and that therefore the deductions in this paper are not valid To forestall this argument it is necessary only to point out that the process was not limited to the scalp, but involved the face, neck and elbow flexures In another case in which the irritant had been applied to the bust, the entire body was involved A patient whose illness had been precipitated by resorcin was sick for six weeks, long after the resorcin could have been active, and the course of the attack was characterized by recurrences without the reapplication of the original offending substance

In all of the patients some general disturbance was present, such as neurasthenia, intestinal derangement, or evidences of anaphylaxis The commonest abnormal conditions were neurasthenia and constipation, while in two instances analysis of the feces showed a protein putrefaction Most striking, however, was the light thrown on the pathogenic mechanism of these cases by therapy In all fourteen the average duration of the attack was sixteen days The average duration in the patients treated locally alone was twenty-two days, while in those receiving general treatment as well, it was just under nine days, or less than half as long The general measures consisted of colon irrigations, enemas, or the use of cathartics or sedatives, according to special indications

It is clear from this brief clinical exposition that two main pathogenic factors were present These were local irritants which were active beyond the site of their application and beyond their period of immediate contact with the skin, and general causes which rendered the skin susceptible to the former In other words, the irritants merely precipitated a reaction in prepared individuals General treatment served to lessen the susceptibility, so that the clinical experiences here outlined serve as experimental evidence favoring the argument advanced in this study

SUMMARY

Eczema and simple dermatitis resemble each other clinically and microscopically Thus eczema, from the standpoint of pathology, is dermatitis, differing from the latter in the clinical sense only in so far as it arises without a demonstrable local cause For the rest, both are dependent on a predisposition which renders the patient susceptible or responsive to the influence of the determining factor A great number of conditions, both general and local, constitute defects which augment susceptibility, while an equally formidable array of known precipitating agents has been compiled, their number steadily increasing at the cost of a diminishing body of unknown ones The distinction between eczema, since it is dermatitis, and what is frankly regarded as dermatitis, is purely academic and is based solely on human limitations Processes which are alike clinically, histologically, histogenetically and pathogenically are identical, wherefore, all that remains of eczema is the fact that it is dermatitis of unknown origin

This being the case, it is scientifically disadvantageous to continue the use of the term The whole class of conditions in question should be divided into two groups, dermatitis of known and unknown origin, respectively, of which the second would represent the ancient eczemas But as such a change would throw a heavy tax on loyalty to tradition and on dermatologic literature, the continuance of the classic term may be allowed with the restriction that it indicates dermatitis, the immediate cause of which remains obscure Eczema would thus cease to be accounted a disease sui generis, and would be looked on as an index of morbidity, the determination of which would become a duty In other words, since its rational treatment would depend on a knowledge of its cause, it would stimulate the study of the dermatosis from the standpoint of internal medicine This would be of benefit to the patient and would hold dermatology to a scientific path from which it tends only too often to be lured by the fascination of glittering, if somewhat unsound, morphologic superficialities

108 West Eighty-Seventh Street

ECZEMA OF EXTERNAL ORIGIN AND ITS RELATIONSHIP TO DERMATITIS

BASED ON A STUDY OF 36 996 DERMATOLOGIC CASES OF WHICH 6 453 WERE CLASSED AS ECZEMA *

FRANK CROZER KNOWLES, M D
Instructor in Dermatology University of Pennsylvania School of Medicine Clinical Professor of Dermatology, Women's Medical College of Pennsylvania
PHILADELPHIA

In May, 1912, I had the pleasure of reading a paper before the American Dermatological Association with the title of "The External Origin of Eczema, Particularly the Occupational Eczemas, as Based on a Study of 4,142 Cases " This study was based on a review of 24,459 cases of diseases of the skin observed, in nine years, in the dermatologic clinics of the Pennsylvania, University and the Howard hospitals During the last five years I have had the opportunity of observing 12,537 additional cutaneous cases in the skin departments of the Pennsylvania and the University hospitals, of which number 2,311 were tabulated as eczema Therefore, during the last fourteen years there have been studied 36,995 dermatologic cases, of which a total of 6,453 have been classified as eczema (14 75 per cent) In the former series of cases, fully one quarter of those tabulated as eczema were of determinable external causation, while in the present group almost one third could be attributed to external factors

It should be recalled that the cases tabulated in the foregoing lists have been classed as eczema because of their chronicity as to course, lasting over a period

---

* Read before the Section on Dermatology at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

of weeks and months, although most of them were exceedingly acute in their clinical appearance Hundreds of cutaneous cases were diagnosed as dermatitis in the hospitals named, particularly those attributable to plant poisoning or acute irritants, in which the outbreak ran a rapid course toward recovery, cure being effected in a few days

The study of the external etiology of eczema may conveniently be divided into three classes the parasitic origin of the disease, eczema from external irritants, exclusive of occupation, and trade eczemas

Investigations into the parasitology of eczema have been made by many excellent observers There is no definite evidence that organisms in or on the skin are causal of eczema, although cocci, usually of the staphylococcus group, no doubt have a decided influence in determining secondary lesions and complicating factors The parasitology of the disease may be summarized by stating that the majority of dermatologists do not regard eczema as due to a specific organism, or as a parasitic disease, the various forms of which conform to different organisms, but the belief is prevalent that bacteria may play an important part in the evolution of the lesion Numerous references on this phase of the subject may be found in a former publication of mine and in the article recently written by Heimann

Eczema of external origin, exclusive of occupation, may be produced by any irritant in a susceptible person, or by prolonged and frequent exposures to an irritating factor in those less predisposed We are all familiar with the many external factors which cause an outbreak, such as injuries, dyes, drugs, friction, etc Those irritants which should be particularly emphasized are iodoform, hair dyes, dyed fur, and cosmetic preparations Iodoform very often gives rise to a spreading inflammation of the skin, particularly when used as a dressing to a raw surface This spreading redness, resembling erysipelas and at times a scarlatina, may not only be evanescent in course but also partake of the character of an eczema, lasting over a considerable period

Paraphenylendiamin, which is the dye used in many hair preparations, is coming more and more to the fore as the cause of a persistent erythematous and vesicular outbreak on the ears, face and neck, which may last over a period of some weeks This dye is also a prolific source of irritation about the neck and the wrists of those wearing brown fur and black pony coats Numerous instances of eruptions are observed in our private work from the use of vanishing creams, so called, and all types of cosmetics Within the last week an outbreak of some weeks' standing, of a papular type, has been seen in my office apparently due to a preparation labeled as "milk weed cream" Outbreaks have been observed from "breast developers" and also from one of the proprietary iodin ointments Lesions from the latter preparations had been present for some weeks when the patients came under observation

Trade eczemas offer a large dermatologic field, and many pages might be written alone on this phase of our subject In my former publication, twenty-nine different trade groups were tabulated in which various irritants handled were causative of an outbreak The eczematous outbreak was found in the following occupations housewořkers, laborers, woodworkers, photographers, printing trade, painters, millworkers, bleachers and cleaners, cloth handlers, tanners, coopers, physicians, dentists, nurses, attendants and those handling drugs and chemicals, workers in sugar, candy and chocolate, bakers, barbers, bartenders or liquor dealers, handlers of oils and greases, handlers of pastes, grocers, plastering, paper and building trades, tobacco workers, furriers and hatmakers, workers in metals and minerals, handlers of dyed materials, fruit handlers, ice and ice cream makers, soap makers, packers, farmers and florists Recently a generalized outbreak of an erythematosquamous type has been observed in five workers in munition factories These men were all exposed to picric acid, alcohol and ether Their portion of the work consisted of putting the wet guncotton into cans The outbreak in each instance had been present for two weeks or more

Nomenclature is one of the greatest faults of our specialty, dermatology There is no more chaotic subject than exactly what eczema is and the dividing line between this affection and dermatitis The remarks made by Zeisler are pertinent to this subject He said that he felt like presenting the etiology of eczema, in a rather paradoxical vein, something like the following When we had a case of eczema of which we knew the cause, then it was not eczema, and when we had a case of dermatitis and did not know the cause, then it was eczema Or again, when we had a case of eczema which readily responded to treatment, then it was not eczema, but simply a local dermatitis, and when we had a case of dermatitis which proved obstinate to our therapeutic efforts, then we were really confronted with an eczema

Willan and Bateman, Biett, Cazenave and Schedel and Hebra assert without qualification the identity of dermatitis of external origin and eczema Fordyce considers that the two are identical clinically and histologically Pusey states that "our difficulties disappear if we accept eczema to be what it is in all of its clinical characteristics — a superficial, simple dermatitis such as might be excited by external irritants" Hartzell mentions that he did not believe that there was any real distinction between many cases of so-called eczema and many cases of chronic dermatitis Hyde stated that "there is no 'eczema' in the absence of dermatitis, is there any dermatitis without some of the accepted symptoms of 'eczema'? The doom of the word is probably written It will survive where it belongs and with no greater repute than attaches to the outworn and the discredited"

Anderson, Fox, Jacquet and Jourdanet add predisposition as a factor in dermatitis of external origin Heimann has recently stated the conclusion that dermatitis and eczema are identical, having the same clinical and pathologic picture

Bowen and, I believe, the majority of dermatologists consider that artificial dermatitis offers no histologic divergences from acute eczema, notwithstanding the view held by Unna that vesiculation is not uniformly characteristic of eczema in the manner that it is of acute dermatitis

After a thorough study of hundreds of cases and a perusal of the literature bearing on the subject, the investigator is forced to the conclusion that it is practically impossible to distinguish between dermatitis and eczema of external causation If the outbreak is caused by certain irritants, such as plants, we call it dermatitis, if by certain other irritants, eczema If it be of short duration and of known cause, we call it dermatitis, if of long duration an eczema The clinical picture may be the same in each, the histologic appearance identical, and yet we place the one under the heading of a dermatitis and the other is classed as an eczema Is not our attitude inconsistent? Should we not take a firm stand and advance a step forward by classing all cases of known external causation, which have heretofore been classed as eczema, under the heading of dermatitis?[1]

CONCLUSIONS

Almost one third of all cases of eczema are of definite external origin About one sixth of all cases of this affection are caused by the occupation of the individual

Micro-organisms play only a secondary role in the causation of the disease

Practically every occupation and every irritant may produce an eczema

The portions of the skin exposed to the irritant determine the site of the outbreak

The eruption not infrequently extends beyond the irritated areas, at times being observed on distant parts of the cutaneous surface and also generally in certain *instances*

The usual type of eruption noted is the vesicular or the erythematosquamous

The eruptions mentioned as occurring in the cases in this article have lasted for weeks months and years, and showed a marked tendency to relapse

It is rather hard to explain the susceptibility of some persons to certain irritants, while others are not affected, excepting on the theory of a pure idiosyncrasy, an anaphylactic tendency causing sensitization of the skin

As dermatitis and eczema of external origin have the same clinical and microscopic appearances, they should be classed under the heading of dermatitis

TWO MODERN METHODS TO BE EMPLOYED IN THE TREATMENT OF CHRONIC ECZEMA *

CHARLES J WHITE, M D
Edward Wigglesworth Professor of Dermatology, Medical School of Harvard University
BOSTON

The etiology of chronic eczema remains still a subject of conjecture Men have held decided views on this question since the disease was first recognized, and to those who seek the details of this historical controversy let me recommend the excellent summary of the subject recently published by Heimann[2] Today there can be no doubt, I think, in the unbiased mind that internal as well as external causes play their respective roles in the production of the disease, and I believe that at the present moment a good many men hold the opinion that the first etiologic step is the sensitization of the skin and that the second is the contact with an external irritant

One might regard this theory as a compromise between the two earlier creeds, that is, the external and internal, but I myself find any other conjecture irreconcilable with the facts All men admit that certain substances, too numerous even to mention, are capable of producing an eczematous eruption on the skin, but this apparent capability is limited, fortunately, to but a comparatively few skins, otherwise many occupations would have to be banished from the face of the earth Granted, therefore, that certain substances are cutaneous excitants, how can we explain the fact that forty-nine men escape all outward inconvenience when the fiftieth man working under exactly the same conditions and handling exactly the same substance in exactly the same manner becomes affected, to such a degree, at times, that further subjection to this substance becomes an utter impossibility? Or, again, how is it possible that a pathologist who has for years dipped his hands into liquor formaldehydi with impunity suddenly becomes incapable even of entering a room where this chemical is stored? Or, once more, how does it come to pass that a botanist who has been poisoned by rhus toxicodendron for many years suddenly finds that he has become immune to the influence of this heretofore noxious oil? Something more than an external irritant is at work in these three not hypothetic individuals just cited Something has happened in the economy of these three men to make them susceptible to a given chemical and again to render one of them no longer a victim to its influence

What this thus far unexplained something is is the elusive x which men are now seeking so diligently, and this something has been the object of my quest for the last two years and more

Following the lead of Schloss of New York, who worked on the urticarias of childhood in 1912, and of Towle and Talbot of Boston, who investigated the subject of infantile eczema in 1913, and of Goodale of Boston, who has studied so thoroughly the question of the pollens in hay-fever in 1913-1914, I have tried to solve this etiologic puzzle by means of cutaneous food inoculations and by the study of the feces

At the end of my first year's investigations I made to the American Dermatological Association a preliminary communication[3] with the following conclusions, based on a study of sixty-four cases of chronic eczema

> From the facts thus recorded and from other investigations not detailed we make the following deductions on the question of food in its relation to chronic eczema at various ages of life
>
> A Eczematous infants usually present in their stools an excess of fat or starch An excess of the former element generally means a moist eczema, of the latter, a dry type
>
> B When eczema is present and neither fat nor starch appears in excessive amounts in the feces the physician should look for susceptibility to egg albumin or to milk or, in default of all these more common causes, to a diminished thyroid secretion
>
> C Susceptibility to egg or to milk can be demonstrated by the new method of food inoculations—a procedure analogous to the von Pirquet test for tuberculosis and the Schick test for diphtheria
>
> D This cutaneous method can be extended to the study of the action of other food elements in eczematous individuals
>
> E Normal people, so far as we have ascertained, do not react to these tests

F In chronic eczema the great majority of its victims seem to exhibit anaphylactic reactions to one or more types of food substances

G This phenomenon, as evinced in the few instances investigated, seems to be present in other diseases, which have been associated in the past with food disturbances, notably urticaria and probably acne vulgaris

H Approximately 20 per cent of eczematous individuals do not appear sensitized to any of the common food types These exceptions may denote that all cases of eczema are not due to food sensitization or that special individual articles of food, not tested by us, may be the causative factors Such exceptions have been demonstrated by pediatrists where, for instance, one child's asthma is produced by English walnuts

I In practically 30 per cent of these eczematous patients one or more of the controls proved positive This sign may be considered analogous to the symptom usually observed in urticaria, i e, dermographism

J In the few cases where both stool examination and cutaneous tests were made there was one contradictory finding Fat was excessive in the stool and negative on the skin, while starch was present in the feces and negative cutaneously Further combined examinations must be prosecuted in the future to strengthen this whole present theory of the relationship of food poisoning to chronic eczema

K One cannot apparently positively tell from the type of eczema present what food elements will give positive skin reactions

About the same time Schloss read before the American Pediatric Society a paper founded on the results of his three years' labor in this field, from which I quote

> *It is unusual to find in one individual idiosyncrasy to one* food substance alone
>
> In nearly all cases of food allergy observed, eczema had existed at some time
>
> Out of eighteen cases of pronounced eczema sixteen showed cutaneous reactions to the proteins of one or several foods (fourteen to egg, twelve to cow s milk)
>
> That the relationship of the food idiosyncrasy to the eczema may be causative is attested by the therapeutic results, but withdrawal of the toxic food is not always followed by a prompt disappearance of the eczema
>
> A great number of people, subjects of food allergy, give cutaneous reactions to toxic foods, and so far as determined, this reaction occurs only in cases of food allergy except in the case of those individuals in whom urticaria factitia is present
>
> Eosinophilia may be present in cases of food allergy
>
> In all cases where complete tests have been made the offending food constituents have been the proteins Guinea-pigs can be passively immunized by the injections of blood or serum from an affected individual
>
> Patients immunized to egg do not remain immune unless large quantities of eggs are eaten continuously
>
> A severe attack of food poisoning renders a patient immune to attacks from the same substance for two to three months
>
> Thus the attacks may be cyclic and repeated tests must be made
>
> Family histories of similar allergy exist for several generations

In the discussion of this paper, J Howland stated that Blackfan had made cutaneous and intracutaneous tests in twenty-three eczematous children and had found them all sensitive to one or more proteins, almost all to egg, most to cow's milk, and two to breast milk Dr J P Crozer-Griffith remarked that in his belief other food substances than proteins could produce eczema

Continuing my first year's plan of campaign, two of my house officers, Dr L T Thaxter and Dr L M Van Stone, have made intracutaneous food tests on many of the persons of both sexes and of all ages who have been treated for chronic eczema in the outpatient department or in the skin ward of the Massachusetts General Hospital during my service The methods of procedure in these cases have been as follows In a certain number the skin was delicately broken by the rotation of a dental burr, while in others an exceedingly superficial incision was made with a clean, sharp scalpel The latter method was finally adopted because it produced less artificial disturbance in the controls of the factitiously urticarial subjects The flexor surface of the arm of the affected individual was cleaned, two parallel rows of four or more incisions were made, and on four of the incisions were placed a drop of cow's fat-free milk, a drop of oatmeal water or of lactose, a small piece of salt-free butter, and a drop of egg albumin (At times more detailed tests of many substances were made) The other four incisions or abrasions were untouched and left as controls A positive reaction consists in the reddening and infiltration and, in rarer instances, of the papulation of the skin If the control incision manifests the same reaction, the test is not considered positive

In this connection I want to emphasize two facts of omission I regret these facts, and in future work shall endeavor to correct them We did not work with the pure proteins of the various foods, and, as a rule, only one test *in* each individual was made It will be remembered that Schloss stated that food allergy may be cyclic, and for this reason he made many tests in his cases This serious omission on my part may account for the many wholly negative examples which will be noted in the following individuals tested — a condition which at one period last winter proved so disappointing that I nearly abandoned further prosecution of this theme

Strickler and Goldberg,[4] who injected various sterile extracts (egg, cow casein, fish, pork, beef, tomatoes and clams) into the skin of normal patients and patients suffering with several different skin diseases, state that no reaction should be considered positive which does not consist of infiltration to the point of papule or wheal formation which must persist for at least forty-eight hours — any reaction of shorter duration they consider spurious and representing only hypersusceptibility They conclude that when confronted with a positive reaction they are forced to believe that the foodstuff employed for injection is in some way concerned with the causation of the affection in question

This is another method, and perhaps from a purely scientific point of view the most exact one to adopt in the future study of this whole question of the etiologic role of food poisoning in the production of eczema

WHOLLY NEGATIVE CASES

Case 1—G C T, aged 23, stenographer Face and neck crusting and fissured, arms, hands thighs and ankles show papules Food tests negative, October 16 and 26

Case 2—K M C, aged 68, laundress Skin dry, red and covered with fine scales

Case 3—J L, aged 65, rubber refiner Duration of disease, two months Neck, face, forearms and lower legs are red, infiltrated, excoriated and crusted

Case 4—L W, aged 14, schoolboy Duration of disease, three years Thickening, lichenification and excoriation of body generally Food tests negative, Jan 21, 1915, and again, Nov 2, 1915

---

[4] Strickler Albert and Goldberg J M Anaphylactic Food Reactions in Dermatology, The Journal A M A, Jan 22, 1916, p 249

Case 5—G T, aged 79, clerk Eruptions of disease off and on for ten years Skin more or less universally dry and infiltrated and the thighs badly excoriated

Case 6—F L, aged 66, housewife Disease present to our knowledge during twenty years The forehead, cheeks and chin are dull red, dry and scaling

Case 7—M K, aged 42, housewife Eczema for twenty years Elbows red, infiltrated and excoriated

Case 8—W F, aged 13, schoolboy Treated by me off and on for eleven years Present eruption consists of small pinhead papules with punctate excoriations Chest, axillae, abdomen and groins affected

Case 9—J M J, aged 34, housewife Disease present during eleven years Present outlook developed five months previously Right ear and cheek and neck are pink-red and finely scaling Hands are red and fissured (uses borax soap and powder and occasionally sulphonaphthol)

Case 10—J B, aged 6, schoolboy Disease six years in duration Pubes and adjacent thighs are red, papular and thickened, flexures of forearms are red, fissured and oozing

Case 11—B E G, aged 7, schoolgirl Both ears are red and oozing

Case 12—M J C, aged 41, housewife Used borax and soapine much Sides of fingers are red, fissured and crusted

Case 13—B P, aged 23, woman stitcher in shoe factory Backs of hands moist and crusting

Case 14—M H S, aged 21, student Moist, crusting patches on hands

Case 15—M M, aged 16, schoolgirl A dry eczema of both hands of two years' duration

Case 16—B T, aged 42, cigar maker Disease present off and on for eighteen months At present, deep-seated papulovesicles (?) on both hands

Case 17—R. S, aged 2 months, a boy with nummular areas of erythema, infiltration and scales over head, trunk and limbs of four months' duration

Case 18—B S, aged 1 year, a breast-fed and very fat girl who has had the disease practically since birth The children's department suggests that some internal secretion is upset The cheeks and chin show fine, pink papules and the groins are red and moist

Case 19—W S G, aged 40, motorman Disease present for four years, more or less of the time A previously dry and excoriated skin was simply erythematous at the time of the tests

Case 20—H A C, aged 42, rubber tire repairer For one year hands have been rough, red and scaling

Case 21—W H, aged 15 months Disease began at age of 6 weeks and has persisted There has been much oozing and crusting on scalp, face and arms

Case 22—G E, aged 7 months Eruption began six months previously, and at the time of the tests there were papules on the buttocks

Case 23—H J W, aged 4 months Patches of infiltration, exudation and crusting on cheeks and extensor surfaces of the arms of several weeks' duration

Case 24—J G, aged 6 months, breast-fed girl Duration of disease, three months The face is erythematous, oozing, crusting and fissuring

Case 25—W F C., aged 20, clerk Fingers have been infiltrated, dry and scaling for seven months

Case 26—B C, aged 15, schoolgirl Disease has been intermittently present for ten years Present attack is three months old and consists of redness and fine vesiculation with some crusting on palmar surfaces of right finger

Case 27—A S aged 38, scrubwoman For eight months September 1, palms and fingers show occasional vesicles and fissures October 20, palms thick and dry

Case 28—E. D, aged 38, housewife. Uses naphtha and borax soaps Duration of disease seven years Palms red dry and scaling

Case 29—S U, aged 50, trained nurse September 14 redness excoriation, fissuring and crusting on top of three toes for two weeks October 5, dull brown, sharply bounded, slightly infiltrated skin

Case 30—M M, aged 62 Eczema for thirty years Whole scalp and adjoining face and large part of body are infiltrated, dry, red and scaling

Case 31—E M, aged 17, clerk Fingers show patches of redness, oozing, infiltration and vesiculation

Case 32—G H, aged 1 year Disease present almost since birth Now behind and under ear is an erythematous, moist, sharply defined area

Case 33—L K, aged 54, housewife Sixteen years' duration Disease present at first on palms and for last two years on legs and thighs At present the palms are very dry and scaling and the legs show excoriated papules

Case 34—N A H, aged 27, saleswoman For five months there has been a crack behind an ear Two weeks ago the process waked up, and now there are moist areas behind both ears as well as dryness and scaling of neck and upper chest

Case 35—S F, aged 3 months Duration, one month Generalized erythema and mild exudation Baby is breastfed

Case 36—S R, aged 13 weeks Breast-fed For two weeks cheeks and forehead have shown minute papulation and furfuration

Case 37—L J P, aged 22, stenographer Off and on for two years At present, face and neck infiltrated, dry, scaling and excoriated

Case 38—A G, aged 27, housewife Backs of hands are dry, leathery and fissured

Case 39—S G, aged 50, shoemaker For one year has had redness, dryness, infiltration and scaling of hands and wrists

Case 40—G W M, aged 62, painter and wood finisher for last eight years Eczema for last five years Face is red infiltrated and scaling

Case 41—D B, aged 4 months Disease present for three months and at present shows a mildly exudative condition of the face and neck.

Case 42—T G, aged 7 months Dirty yellow crusts on both cheeks for last two weeks

Case 43—G M S, aged 18 schoolgirl Skin of thumb dry, infiltrated, scaling and fissured for six months

Case 44—M A G aged 48, housewife Eczema "for years" Left hand and fingers edematous Skin excoriated and shows many superficial pustules

Case 45—J J W, aged 9, schoolboy Child painted himself red and eruption appeared and has persisted Whole face and both arms are covered with an almost coalescent excoriated, papular eruption

Case 46—J C F, aged 61, trolley car conductor Large areas of redness, infiltration and scaling over major portion of trunk and extremities

Case 47—J R, aged 1 year Breast-fed Face and ears have been red, excoriated and exuding for one month Second attack

Case 48—M G, aged 11, schoolgirl Eczema "for years" Skin at present generally red, thickened and fissured Face erythematous and scaling

Case 49—M E B, aged 26, teacher For last three winters eczema has appeared Now there are small papules on hands forearms, face, neck and upper chest Elsewhere the skin is dry and furfuraceous

Case 50—J T, aged 20 months Duration three months Crusts and fissures on face and scalp

Case 51—P S, aged 65, wool weaver For one year scrotum has been itching, red and infiltrated

Case 52—W S, aged 47, cigarmaker Hands dry and scaling for previous five months

Case 53—L R. S, aged 53, housewife Four years' duration Crusting lesions on scalp, neck and chest

Case 54—H S, aged 3 months Six months' duration Forehead and cheeks are oozing and crusting

Case 55—H L S, aged 35, woolen weaver Disease present for four months At present occiput, palms, feet and toes show sharply defined areas of redness, thickening, fissuring and small superficial pustules

Case 56—J S, aged 28 Housework. Eczema "for years" Palms now show irregular, ill-defined areas of mild thickening with erythema and tendency toward fissuring

Case 57—R B T, aged 66, housekeeper Duration one month A general erythema over trunk, limbs and face

Case 58—E B, aged 6 weeks Breast-fed and vomits after feedings For two weeks there have been miliary papules over both cheeks and in scalp

Case 59—J T, aged 62, cutter in shoe shop Disease evident for four months, and at present face is dusky red, dry, infiltrated and scaling

Case 60—M F aged 23 Housewife who uses soapine and sulphonaphthol Backs of hands and fingers are very harsh, thickly infiltrated, very dry, and covered with long, deep fissures

Case 61—H W D, aged 58, bartender Five months' duration Back of ears, neck, arms, hands and ankles dull red, infiltrated and scaling

Summarizing these sixty-one cases of eczema which, on one examination, have given negative reactions to all the food substances inoculated, we find twenty-five examples, or 40 per cent, of the moist, oozing, crusting type, twenty-nine, or 47 per cent, of the red, infiltrated, *dry or scaling variety, and seven, or 11 per cent*, of the papular kind

WHOLLY POSITIVE CASES

Case 62—M G, aged 9 weeks Breast-fed Cheeks finely papular

Case 63—A B, aged 26, male stitcher in shoe factory Duration one year Process started with vesiculation of soles and skin and is now infiltrated and fissured

Case 64—J F K, aged 4 Eruption appeared one week after birth and now appears as fine, bright red papules on scalp, neck, chest and buttocks

Case 65—H C, aged 40, barber A few papules and vesicles are present on index finger

Case 66—A S, aged 26, housewife Five months' duration Hands always worse after immersion in water Pinhead vesicles persist on fingers

Case 67—M S, aged 24, housewife For nine months *patient has had infiltration and vesicopapules* on backs of hands and fingers

Case 68—S T, aged 43 Pick and shovel Eight months' duration Skin of legs shows sharply bounded, red, glazed and dry infiltrations

Case 69—E M, aged 6 months For four months cheeks and scalp have shown deep excoriations and bloody crusts Two months later the scalp was well and the cheeks dry, pink and scaling

Case 70—F T, aged 6 Disease has persisted six months and at present the skin of eyelids, ears and scalp is infiltrated, crusting and excoriated

Case 71—W C C, aged 42, chauffeur Eczema for seven years The lower half of one leg is moist, red, and apparently without the horny layer

Case 72—L S H, aged 48, baker Two months previously the lower leg was infected and now the skin is red, infiltrated and papular

Case 73—I R, aged *3½ months The first child had* eczema also Patient breast-fed and for two months the cheeks, forehead and anterior part of scalp have shown scattered coalescent papules, some of which are excoriated and oozing

Case 74—T K, aged 7, schoolboy Duration three weeks A prurigo-like eczema

Case 75—F L, aged 10 months and bottle-fed for last four months Following an earache of one week without any applications the skin around left ear and of cheek broke out into papules and masses of redness and crusting

Case 76—M C S, aged 12, schoolgirl Skin generally dry and harsh, scalp dry and finely scaling, and pinhead papules generally over the whole body

Case 77—I S, aged 8 months Bottle-fed Two weeks' duration Skin of back and flanks very red and finely papular

Case 78—H M, aged 7 months Breast-fed Eczema for eight weeks *At first vesicular and now the* skin of face is reddened and thickened

Case 79—L M, aged 30, housewife Disease present for four years An attack observed after the use of soapine, and another, three months later, following the use of naphtha soap

Case 80—P D, aged 26, barber Eruption present for eleven months

Grouping these nineteen cases which, on one examination, reacted positively to all the food types inoculated, we find nine, or 50 per cent, of the moist variety two, or 10 per cent, of the dry sort, and six, or 33 per cent, of the papular kind (The type of one case is not recorded)

CONTRADICTORY CASES

Case 81—E G, aged 45, housewife Uses naphtha soap, washing soda and soapine Eczema comes and goes October 21, fingers red and swollen and paronychia is present Food tests are negative October 27, food tests positive

Case 82—M E M, aged 18, stitcher in overcoat factory Eight months' duration October 10, both hands show large areas of reddened, dried and exfoliated skin Food tests positive November 10, treatment heals but does not cure Food tests negative

Case 83—F G, aged 1 year Face, scalp, back and lower arms are red, infiltrated, oozing and crusting October 20, food tests positive October 22, food tests all negative

These three cases are naturally too few in number to be of any value statistically, but for the sake of uniformity let us record two, or 66 per cent, moist examples, and one, or 33 per cent, dry and scaling

CASES POSITIVE TO ONE OR MORE ELEMENTS

Case 84—N H, aged 5 months, breast-fed boy Disease evident for five weeks Face and scalp are a mass of excoriations and crusts Albumin +

Case 85—H K, aged 5 months Breast-fed Intertrigo for three months, general eruption for two days consisting of flat-topped, small-sized, pink papules on forearms, trunk and legs Fat +, starch +

Case 86—E M G, aged 73, housewife Both feet show areas of redness, scaling and fissuring Fat +

Case 87—J M, aged 26, bricklayer Palms are moist, oozing, crusting and fissuring Fat +

Case 88—R H aged 16 months Second attack similar in nature to the first, one year previously Face, back of hands, and bends of knees are red, moist, oozing and crusting Milk +, egg albumin +

Case 89—I M, aged 3 Duration perhaps a year Both arms are raw Child much neglected Starch +

Case 90—M L R, aged 8 months, breast-fed boy Eruption present almost from birth Buttocks show fine papules and excoriations Mother says baby always breaks out after eating eggs Egg albumin +, wheat +

Case 91—B F, aged 45, housewife One year's duration Palms and fingers are infiltrated, exuding and crusting Starch +

Case 92—*J T C, aged 60, teamster Ten months' duration* A similar condition two years previously There is a small, oozing and crusting area on right palm Fat +, starch +

Case 93—B P, aged 17, woman cementer in rubber factory For six months face neck and hands have been red rough, thick and scaly Fat +, starch +

Case 94—R K, aged 23, housewife Duration one year Fingers and palms are patchily red, vesicular, crusted and fissured Fat +

Case 95—E B, aged 33, housewife Afflicted with eczema for twenty-five years, usually beginning in August and lasting until the advent of cold weather Inspection shows oozing and fissuring of elbow and abdomen Fat +

Case 96—T M, aged 38, carpenter For twenty years man has had, despite much treatment from many doctors, coarse, flat-topped, red papules on cheeks and nose Albumin +, fat +

Case 97—P F C, aged 49, shipper A similar attack one year ago Three weeks previously man swept out a freight car and felt choked by the dust, and the skin prickled Now the left face and neck are red, moist, and crusting Fat +

Case 98—O C., aged 10, schoolboy There are infiltrated and excoriated papules on deltoid areas and on abdomen Albumin +

Case 99—N L, aged 16 months Cheeks and ears are erythematous and mildly exudative Albumin + +

Case 100—D J S, aged 3 months, breast-fed boy Duration two months Both cheeks show indefinite, pink, dry and scaling areas Fat +

Case 101—J M, aged 45 The face, neck and ears are bright red and infiltrated and in places oozing and crusting Fat +

Case 102—M L P, aged 1 year, breast-fed boy Scalp and face red and moist Albumin + + +

Case 103—R. M, aged 7 months Duration six months A generalized vesicular eczema, most emphasized on face, scalp, neck and upper chest. Albumin + + +

Case 104—M S, aged 6 months The skin of face, ears, trunk and arms is brilliant red, oozing and excoriated Albumin +

Case 105—I S, aged 3 This girl has spent more or less of her life in the skin ward Whole body red—at times moist, at others dry and scaling Albumin +

Case 106—M C S, aged 12, schoolgirl Skin is generally dry and harsh and easily irritated There are pinhead papules over whole body Fat +, starch +, milk +

Case 107—T J G, aged 21 months Eighteen months' duration Right side of face is pink and moist and shows a few papules Albumin + +

Case 108—S H, aged 3 months For two weeks scalp and upper part of cheeks have been erythematous, vesicular and crusting Albumin +

Case 109—H V, aged 8 months Duration three months Subacute exudative condition of face, scalp, neck and upper chest Albumin + +, starch +

Case 110—R C, aged 2 months, breast-fed girl Vulvar region is claret red, edematous and moist Fat +

We find, therefore, in this partially positive group, nineteen, or 75 per cent, of moist cases, four, or 15 per cent, of dry, and four, or 15 per cent, of papular Studying these cases over more in detail, we note in the nineteen moist examples of eczema ten anaphylactic to egg albumin, seven to fat, four to starch, and one to milk Of four cases of dry eczema, one reacted to egg, four to fat, two to starch, and one to milk Of four papular cases, two proved sensitive to egg, two to fat, and two to starch Thus we find that out of thirty-six positive reactions in these twenty-seven sensitized individuals, thirteen, or 36 per cent, were due to fat, and thirteen, or 36 per cent, to albumin — in other words, we must conclude that 72 per cent of our eczema patients are susceptible to egg albumin and butter fat, while only 22 per cent react to starch and barely 6 per cent to milk

These various percentages differ considerably from those recorded in my first year's communication, but perhaps we have not progressed far enough in this work to make our tables of any permanent value as yet There is, however, one very striking and to me inexplicable and rather discouraging fact in comparing my work of the previous two years, and that is the great proportion of wholly negative results recorded this year, that is, 55 per cent against only 20 per cent last year I have no reasons to offer for this disappointing discrepancy I cannot believe that the reason lies in the fact that different men made the tests, for this part of the work of last year was done by two or three men, while the same holds true for the present series Nevertheless, I have not lost faith in the procedure or in its probable value, which I believe will be proved in time Let me repeat that the pediatricians state that the test to be of conclusive value must be performed more than once on the same person

Before leaving this part of my theme, I wish to state that I am not trying to prove that all cases of eczema are due to food idiosyncrasy My intent is to bring to notice the fact that in certain persons this anaphylactic phenomenon is present and in the course of time to be able to prove that this state is responsible for the susceptibility of these persons to external irritants which remain innocuous to their fellow workers and fellow men

STOOL EXAMINATIONS

There is perhaps another method of attacking this question I refer to the macroscopic and microscopic examination of the feces From this procedure we can learn whether or not the digestive and assimilative powers of eczematous individuals are on a par with the normal standard These examinations have been made by Dr Lewis Webb Hill and by my house officers, Dr Thaxter and Dr Van Stone

The methods of fecal examination are too well known to require any explanation on my part I shall merely state that the usual procedures have been followed in the following cases

CASES WITH NORMAL STOOLS

Case 111—J A T, aged 51, vice president Duration of disease fifteen years Attacks appear whenever patient is overworked At present a widely distributed, very red, almost confluent, papular eczema

Case 112—J M, aged 45 Face, neck and ears are bright red, infiltrated and in places oozing and crusting Fat +

Case 113—T J A, aged 53, bottle washer Disease present for four months Face ears, neck, chest, abdomen thighs, buttocks and soles of feet are red, infiltrated and scaling

Case 114—D F, aged 5 Eczema has been present for seven months and is rather generally distributed Skin is slightly reddened, roughened, infiltrated and fissured and a few papules are evident.

Case 115—M J D, aged 74, housekeeper Skin shows areas of redness, roughness infiltration and excoriations

Case 116—J G F, aged 61, street railroad conductor Duration nine weeks Large areas of redness, infiltration and scaling are present. Food tests are negative

Case 117—J R, aged 20 months, breast-fed girl Child observed in second attack Face and ears are red, excoriated and exuding Nits are present Food tests negative

Case 118—M L P, aged 1 year, breast-fed boy Face and ears show pink-red papules Albumin + + +

Case 119—M S, aged 11, schoolgirl Eczema "for years" and at present the face is red, dry and furfuraceous and the skin of the body is generally red, thick and fissured Food tests are negative

Case 120—H M, aged 9 months Duration of disease eight months Breast fed Skin is reddened and thickened and in places moist Food tests are all positive

Case 121—R M, aged 7 months Disease present for six months and consists of generalized vesiculation, especially on scalp, face, neck and upper chest Albumin + + +

Case 122—J T, aged 62 Cutter in shoe shop Duration four months Face is dusky red, dry and furfuraceous Food tests are negative

Case 123—M F, aged 23, housewife Patient seen in second attack of disease Backs of hands and fingers are thickly infiltrated, very harsh, very dry and covered with long deep fissures Food tests are negative

Among these thirteen persons with normal stools, seven, or 54 per cent, exhibited eczema of the dry type, four, or 30 per cent, of the moist variety, and two, or 15 per cent, of the papular sort

CASES WITH EXCESSIVE FATS OR SOAPS IN THE STOOLS

Case 124—P F, aged 11 months Disease present for ten months Breast-fed for 3½ months Face and left shoulder show a few persistent areas of red, slightly infiltrated, dry and slightly scaling skin

Case 125—A C, aged 49, clerk Four months' duration Palmar surfaces of fingers are red, dry and scaling

Case 126—A C, aged 60, physician Disease has been present intermittently for six years, and for the last three months the patient has observed a dusky edema of eyelids, pink-red maculopapules on forehead, and redness, infiltration and scaling on several fingers

Case 127—H W D, aged 58, bartender Five months' duration Ears, neck, arms, hands and ankles are dull red infiltrated and scaling Food tests are negative The stool shows microscopically a rare globule of free fat, a small amount of soap and an occasional starch particle

Case 128—M S, aged 6 months Face, ears, neck, chest, trunk and arms are brilliant red, oozing and excoriated Albumin + The microscope shows a slight amount of fat and a considerable degree of soap

Case 129—I S, aged 3 A frequent visitor to our skin ward The whole body, including the face and scalp, is red and infiltrated, in places dry and in places moist Albumin + Macroscopically a typical soap stool, microscopically there is a considerable amount of neutral fat and an excess of soaps

Case 130—M C S, aged 12, schoolgirl The skin is generally dry and harsh and easily irritated The scalp is dry and finely scaling There are pinhead papules generally over the whole body Fat +, starch +, milk + Microscopically the stool shows a moderate excess of soaps

Case 131—M E B, aged 26, teacher Disease present for last three winters, absent in summer Face, neck, upper chest, arms and hands show small papules some of which are excoriated and oozing while others appear dry and furfuraceous

Case 132—F Q, aged 20, brick maker Disease for sixteen months Face, scalp, trunk and extremities show areas of infiltration, papules, excoriations and crusts Some cellulose and a small amount of soap are present in the stools

Case 133—J T, aged 20 months Disease of three months' duration Greasy crusts on scalp, and crusts and fissures on face Food tests are negative Microscope shows a moderate excess of soaps, but no free fat

Case 134—P S, aged 65, woolen weaver Man has had an itching, red and infiltrated scrotum for one year Food tests are negative Stools are not formed and gas fermentation is present Microscope shows a moderate amount of soaps

Case 135—W S, aged 47, cigar maker Man has had previous attacks of eczema which disappear when occupation is given up Present eruption apparent for five months The hands are dry and scaling Food tests are negative The microscope reveals a very small amount of neutral fat

Case 136—E G, aged 7 months Breast-fed Duration two months Over the whole face are thick, dirty, heaped-up crusts and excoriations There are also a few papules on both arms November 30, and December 8 and 13, a moderate amount of soaps were found microscopically

Case 137—A T B, aged 43, housewife A varicose eczema which has appeared also in 1908 and 1911 A small amount of free fat occurs microscopically

Case 138—L R K, aged 53, housewife A recurrent eczema At present there is crusting on scalp neck and chest Food tests are negative The stool is foul, brothy, semisolid with neutral reaction Considerable excess of soaps and moderate excess of starch are present

Case 139—T J G, aged 21 months Disease evident for eighteen months Right side of face is pink and moist and shows a few papules Albumin + Stool is strongly acid, loose, foul, brothy, and shows gas bubbles A few neutral fat droplets are present as well as an excess of soap A fermentation type of stool with moderate fat and sugar indigestion

Case 140—S H, aged 3 months Duration two weeks Scalp and upper cheeks are erythematous, vesicular and crusting Albumin + Stool is soft, yellow, very acid and contains many soft small curds, considerable mucus and considerable fatty acids and soaps

Case 141—H S, aged 3 months Duration of disease the same Forehead and cheeks are oozing and crusting Food tests negative Stools are rather watery, brownish-yellow, slightly acid and contain a small amount of fat

Case 142—I S, aged 8 months Bottle-fed Disease two weeks old Skin of back and sides very red and shows pinhead papules Food tests are all positive Five examinations of the stools revealed many soap suds, some soft curds, some mucus The sixth test when the eczema was practically gone revealed a normal stool

Case 143—H L S, aged 35, woolen weaver Duration four months Occiput, palms, feet and toes show sharply defined areas of redness, thickening, fissures and small pustules Food tests are negative Stool contains a moderate excess of soap

Case 144—J S, aged 28 Housework Disease present for years Palms show irregular, ill defined areas of mild infiltration with redness and tendency toward fissuring Food tests are negative Stool is musty and contains a large excess of neutral fat and of soap and of fatty acids

Case 145—R B T, aged 66, housekeeper Duration, one month General erythematous condition of face, trunk and limbs Food tests are negative Stool is black, foul, frothy, almost fluid, and contains a moderate excess of soaps

Case 146—E B, aged 6 weeks Breast-fed girl Two weeks' duration There are minute miliary papules over both cheeks and on scalp Diaper region is generally reddened Food tests are negative Stool is spongy and yellow, contains curds and a moderate increase of neutral fats and soaps

Case 147—J E H, aged 80, manufacturer A mild but very chronic and persistent erythematous and infiltrated eczema of the feet Stool is foul, alkaline and pasty and contains a slight excess of soap

Case 148—A W S, aged 31, physician An infiltrated, rather cornified condition of the palms of three years' duration Stool shows a very large excess of neutral fat and an enormous excess of soaps and fatty acids The microscopic field seems to be composed of fat

Case 149—C F, aged 6 months A girl breast fed for six weeks only Eczema present for three months The cheeks are fiery red and moist The hands, forearms, lower legs and feet show intracutaneous papules The stool shows a very rare neutral fat droplet and a moderate excess of soaps and fatty acids

Case 150—R F G, aged 6 months, a breast-fed girl Duration 3½ months Cheeks show small areas of redness, moisture and excoriation Stool is very acid in reaction and shows a moderate excess of neutral fat and a very large excess of soap and fatty acids

Case 151—H K P, aged 59 An eczema of many years' standing Palms and soles thickened and cornified in definite areas Stool is liquid, foul, brothy, strongly acid and contains a large amount of cellulose and a slight excess of neutral fat

Case 152—E L Y, aged 2 years Duration, approximately eighteen months At first marked egg anaphylaxis was present but eventually outgrown For last few months disease has been present in scalp which at present is buried under a mass of white, granular scales Stool shows a large excess of soap

Of these twenty-nine patients exhibiting an excess of fat or soaps in the feces, fifteen, or 51 per cent, showed a dry type of eczema, nine, or 31 per cent, a moist, and eight, or 18 per cent, a papular

CASES WITH AN EXCESS OF STARCH IN THE STOOLS

Case 153—F G, aged 1 year Scalp, face, lower arms and back are red, infiltrated, oozing and crusting Food tests are all positive, October 20, and all negative two days later Stool shows a large excess of undigested starch

CASE 154—H V, aged 8½ months, a breast-fed boy Duration three months Scalp, face, neck and upper chest are mildly exudative Albumin + +, starch + Stool is green, loose, strongly acid and contains a moderate excess of starch—"a typical stool of carbohydrate indigestion"

CASE 155—R C, aged 2 months, a breast-fed girl Disease present since birth Vulva is red, moist and edematous Food test is positive to fat The stool shows a typical fermentative diarrhea due to excessive carbohydrate fermentation

CASE 156—L R K, aged 53, housewife Disease four years old and shows crusting on scalp, neck and chest Food tests are negative Stool is foul and brothy and contains a considerable excess of soaps and a moderate excess of starch

In the four individuals whose stools contain an excess of starch, all displayed the moist variety of eczema

Summarizing eczematous individuals from this point of view, we find that 28 per cent passed normal feces, 63 per cent stools containing an excess of fat, and 8 per cent stools exhibiting a surplus of starch These are significant figures

Analyzing the last group of patients, do we find, when both skin tests and fecal examinations have been made in the same individual, that these two methods of study always reveal similar results? I regret to say that we do not In the patients with normal stools one showed a positive cutaneous test to all the types of food inoculated, and one a test positive to fat In the fatty stool group, ten patients showed cutaneous tests negative to all types of food inoculated, and two positive to starch In the starchy-stool group, one individual exhibited tests wholly negative These discrepancies are regrettable rather than vitiating to the object of our study—mere inability to digest and assimilate all types of food ingested does not necessarily mean that the individual has become sensitized to these foods, and yet the same inability may possibly play a rôle in the cause of the individual's eczema

CONCLUSION

From the detailed results it is evident that a goodly proportion of persons affected with chronic eczema show sensitization to the various types of food and that a much larger percentage are unable wholly to digest all the elements of the foods they eat

I cannot present exact figures showing the comparative percentage of improvement or of cures resulting from the correction of errors of diet in these eczematous patients as revealed by these two methods of examination—I can merely assert that chronic eczema should no longer be the bugbear that it was, in fact, with the aid of these two methods, one should expect to cure and cure reasonably quickly the great majority of these patients who present themselves for treatment I believe that this assertion could not have been made with equal truth two years ago

---

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS HEIMANN, KNOWLES AND WHITE

Dr Ernest Lewis McEwen, Chicago The sources from which the medical student gains his knowledge are, first the teacher, and, second, the textbook I have always found the teaching of the subjects of dermatitis and eczema extremely difficult, largely because the textbooks handle them in an unsatisfactory way They make the chief distinction one of etiology, eczema is caused from within, and dermatitis from without As a matter of fact, these cutaneous disorders both have external and internal factors of origin, and in the absence of clinical differences the student is wholly at sea as to what constitutes eczema and what dermatitis I have been on the lookout for some one to write a textbook on dermatology who will have the courage to abandon the old methods of discussing these subjects and to strike out along new lines One or the other of these two terms will have to be abandoned in the interest of clearness, and despite the fact that the term eczema has been used so long and so extensively I do not feel that we must necessarily retain it I believe Dr Heimann's conception of these two disorders is very close to what will eventually be accepted If eczema and dermatitis are identical then we must correct the nomenclature, one or the other term must be eliminated If such a change were made for the sole purpose of helping the student to a better understanding of a difficult subject it would be amply justified In searching for the causes of these cutaneous disturbances we have a wide field to cover and much earnest work must be done Dr White is following a promising lead and I believe we may expect valuable findings from his work The internal factor is the great unknown quantity which all must seek in these diseases, if we are to put them on a truly scientific basis

Dr Jay F Schamberg, Philadelphia I agree in the main with the propositions expressed by Dr Heimann We are all instinctively worshippers of tradition, particularly medical tradition, and we reluctantly give up such a term as eczema We have, however, during the course of many decades, gradually lopped off from this a comprehensive group of diseases like scabies, eczematoid, ringworm, etc, and this pruning will continue The most scientific classification of skin diseases is that which is based on etiology If it is definitely determined that a certain type of eczema is due to the poisoning from ivy or primula, that another is due to food, it is clear that they are separate and distinct conditions, although we may not be able to differentiate them always clinically The etiologic factor, it seems to me, is the dominant one, for through its recognition the cure is effected For the past year or two, through the activities of Dr Strickler, one of my associates, we have been trying to study the question of food sensitization and its relation to eczemas We must be prepared to realize that with some food substances, such as cow caseins and egg white, we are dealing with very pure proteins, and one must be warned against regarding all reactions with such rich protein substances as necessarily indicating a relationship to the eczema under consideration We not infrequently see reactions from milk, and yet on the exclusion of milk no favorable result On the other hand, remarkable results are sometimes achieved To produce an adequate protein extract of meat it is necessary to use an alkali, and it is important to determine that the alkali does not induce of itself a reaction in the skin These protein extracts must later be subjected to analysis for the determination of nitrogen to make sure of the amount of protein they contain We must be certain of our methods and technic before we can expect to arrive at results which will be really indicative of the true state of affairs Many persons are susceptible to certain external irritants by reason of an inherent susceptibility which others do not possess One man may be highly susceptible to poison ivy, for example, while his neighbors may be insusceptible to it I recently saw a girl of 14 who for three or four years has suffered from several severe attacks of ivy poisoning each year, perhaps three months of each year were spent in recovering from these attacks I determined to try to immunize her and ordered a 1 per cent tincture of rhus toxicodendron in 100 c c of menstruum, of which she was to take 3 drops after each meal gradually increasing the dose At the end of one month she was taking 60 drops after each meal Since then she has not only been able to pass poison ivy at close range, but also to touch it without bad effect The result was so striking that I expect to follow this method in other cases and I hope that some of those present will give it a trial

Dr Henry Truman Byford, Chicago Formerly I suffered from patches of eczema on the lower limbs, sometimes lasting for weeks, sometimes only a few days I began experimenting with my food and found that I would usually improve rapidly by cutting out the starches, and subsequently I found that by eliminating the fats the eruptions would always disappear very promptly After trying various diets, I concluded that milk and eggs were the causes, but that they did not act except when the stools contained fat or gave evidence of carbohydrate fermentation Hence, in my case the cure consists in keeping the alimentary canal in a normal condition and in eating the offending proteins in quantities that the system needs and is prepared to metabolize Acting on this belief I have no more trouble except about once a year or so when I grow careless and get caught with a beginning eruption In these rare attacks the itching subsides as soon as I begin to act on this belief, and the unoffending rash rapidly fades away Hence I consider the cause of my former attacks of eczema to have been deranged digestion that interfered with the complete digestion of certain proteins and thus resulted in anaphylaxis

Dr Richard L Sutton, Kansas City, Mo Dr Heimann and Dr McEwen suggest that we discard the term eczema, and consider all lesions now grouped under that heading as instances of dermatitis I wish to arise to a point of order After all of the various interlopers such as scabies, infectious eczematoid dermatitis, ringworm of the palm, and a host of other diseases have been thrown out, I believe there still remains a small group of cases, reflex if you like, but entitled to be considered as idiopathic nevertheless, which belongs in this category Dyer's preputial type, and Whitefeld's flexural variety may be taken as more or less typical examples Following Dr White's suggestions regarding the role excessive fats and starches and anaphylaxis play in the causation of infantile eczema, my therapeutic results in this disorder have been much better during the past two years than they were prior to that time It would be extremely unwise to consider all cases of eczema as examples of dermatitis, pure and simple Clinical observation, research, and frequent discussions will go far toward clearing up the obscure points in question

Dr E D Sager, Cleveland I think that in many instances these eczematous eruptions are the result of faulty metabolism, and my routine treatment in many cases consists of salicylate of mercury, in combination with taraxacum and an alkali in order to overcome the acidosis that is almost invariably present Tests of the blood and stomach contents should first be made Externally, I have had very good results with the Finsen light

Dr Michael Leo Ravitch, Louisville, Ky In regard to the classification of eczema, I agree with Dr Schamberg, and I do not think the term should be discarded Rather, I would divide the eczemas into two classes, i e, those due to internal causes I would call true eczema, and those due to external causes, such as occupation, mechanical or chemical irritants I would call dermatitis I believe that faulty internal secretions have much to do with the production of true eczema The sensitization of food tests carried on under Dr White ought to be commended While nothing definite has yet been established, we may yet learn a great deal from such experiments

Dr Andrew P Biddle, Detroit I would call attention to the treatment of chronic eczema from another point of view I agree with Dr White that the food element has much to do with its causation, but I have studied the subject from a different angle I have associated with me men who are specialists in other lines, internal medicine, gynecology, roentgenology, etc, and in as many cases of chronic eczema as possible have submitted the patient to a thorough general examination Our investigations have shown almost invariably some degree of ptosis or stasis of the bowel, and frequently, in women a displacement of the uterus In short, we have usually found some evidence of stasis in the ileum or colon, and, when we have succeeded in correcting this condition, we have aided materially the cure of eczema I am firmly convinced that the only way that we shall be able to cure chronic eczema is to find the underlying predisposing cause and have the condition corrected

Dr Ernest Dwight Chipman, San Francisco I was much impressed with the parallelism of the papers of Drs Heimann and Knowles They both lead back inevitably to the doctrine of cutaneous reactions which indicates that the same cause may provoke different reactions in different individuals, and that the same eruption may be provoked by most diverse causes in predisposed subjects One of the older French writers aptly remarked "There is no eczema, only eczematous" Dr White's paper was of particular interest to me because it emphasized one of the points which I tried to bring out in my paper on dietetics, namely, that while not every skin disease demands dietetic treatment those which do require such care do so for some definite reason and every contribution to our knowledge of fundamental dietetic indications relieves us by so much of the tendency toward haphazard feeding

Dr John G Burke, Pittsburgh I should like to mention two instances where one of twin babies had a vesicular eczema, the mate in both cases being entirely free from an eruption The first set were nursed at the breast and the second set were both receiving the same modified milk mixture As both these children received the same care and attention and the same food as its mate, if eczema is due to an external irritant or to an inherited weakness of the skin, or to the skin being sensitized by the food, why did one child have the eczema and the other twin escape it?

Dr James Moore King, Nashville, Tenn Several years ago I was very much impressed with the effect of milk on a child The patient was a boy with recurrent attacks of eczema, the milk would be withdrawn from his diet and he would get almost well, then he would resume his milk and have a prompt recurrence of his eruption Diet unquestionably plays a great part in eczema Whether the cause is due to the waste products of the food or to a separation or dissociation of the food molecule we do not know but it will probably be found to be a split protein which produces anaphylaxis or sensitization Urticaria is the result of various causes, and I see no more reason for giving up the term eczema than that of urticaria Many years ago Dr Isadore Dyer called attention to a form of eczema associated with adhesions about the prepuce in male infants in these cases I have found that circumcision gives almost immediate relief

Dr Lloyd Warren Ketron, Baltimore I should like to ask Dr White if he has used the intradermal method of testing the sensitiveness of the skin to these proteins? I did this with milk in about twelve or fifteen cases of skin diseases as well as normal cases and found that they all reacted

Dr. Isadore Dyer, New Orleans I have views on this subject somewhat divergent from what has been said Eczema has always appeared to me to be in most cases a condition rather than a distinct entity, and that if we take that view of it we could handle it better One difficulty is that the term eczema, almost ever since its origin, has been used as an omnibus both by the profession and the laity, and we have come to regard it as a generic term To my mind the word implies a catarrhal condition Our conception of a catarrhal condition in other organs than the skin is very clear, and my conception of eczema is that of a catarrhal condition in the skin itself That there are conditions of the skin which properly fall under the term of eczema has been generally appreciated I refer especially to the types of eczema which are called reflex, such as the type we see in infants which appears shortly after birth and lasts weeks or months, where the eruption will disappear and recur, presenting all the evidences of a catarrhal condition To me, no other term than eczema can be employed to define the condition, and we can find no excuse for calling it a dermatitis Its causes are varied, but nearly always the cause is reflex The adhesions of the foreskin causing reflex eczema have already been referred to by Dr King, and that condition as a cause of eczema in male infants has been repeatedly verified by me during the past twenty-five years since it was first suggested by me as the chief cause of reflex eczema in male infants

Dr Samuel E Sweitzer, Minneapolis In the teaching of this subject it has been my custom to classify all cases of known origin as dermatitis and all cases of unknown origin as eczema I sometimes have been inclined to believe that the cases I recognize as eczema differ somewhat from those I regard as dermatitis

I was very much interested in Dr White's paper regarding diet in infantile eczema In our clinic, we refer every child with eczema to the pediatrist for dietary regulation, and we do not get any results in those cases until the diet has been regulated In Minneapolis I have been struck with the increased number of cases of eczema which are due to a mild ichthyosis These eruptions appear in the winter and disappear in the summer, and I have found that these cases have responded very well to local treatment and also to the administration of thyroid We have also been on the lookout for alveolar abscesses in connection with chronic eczema and have endeavored to trace a connection between the two conditions

Dr H H Hazen, Washington, D C I do not know whether we are justified in omitting all mention of external parasites, especially bacteria, as exciting factors in some of these cases Drs Ormsby and Mitchell demonstrated the existence of such cases In children with discharging ears we often see a true vesicular eczema where the pus has run over the skin In children who sleep together we often see a true eczema extend from one to the other, showing evidence of a definite contagion There is another common type that begins with a small vesicle, if you will remove the top from one of those tiny vesicles and thoroughly cauterize the lesion, you will prevent the development of other vesicles I have taken the contents of such a vesicle and inoculated myself with them and have been successful in causing an eczema This has led me to the belief that in some of these cases there is a bacterial infection, while in others there must be a predisposing cause In regard to the observation made by Dr Biddle I would say that during the past two years we have roentgenographed several hundreds of patients, and in almost every instance we have found some degree of abdominal ptosis, so that I have come to the conclusion that we must not attach too much importance to this factor In regard to the intradermal injection referred to by Dr White, it would be interesting to try the final food products and see what they would do, as Dr Ketron has suggested to me

Dr H C Baum, Syracuse, N Y This question of nomenclature has brought out very divergent views I myself do not see that it matters very much provided we keep the fundamental nature of the trouble in our mind For years we have taught that all so-called eczemas were examples of dermatitis, and the latter we divided into two groups, one of known cause, the other unknown Dr Heimann has crystallized these thoughts in his paper and fortified them with pathologic evidence Dr White and his associates have opened up a new field, and I think we are all hopeful that its further development will aid greatly in the care of these patients There is one aspect of the subject to which I would like to refer, namely, that of diet Some patients cannot tolerate starches unless something is given to aid in the digestion of the starches and the same is true of certain protein substances After all, Nature is the best physician and if we go back to Nature and put our patient in a high state of physiologic health, he will do better than if we eliminate this and that article of diet and neglect his general condition

Dr Franklin W Cregor, Indianapolis Possibly the physiologist might help us in clearing up these so-called anaphylactic reactions Years ago Crocker called attention to our inability to explain the blush areas anatomically, while the more recent theory is that anaphylaxis may be attributed to the blood platelets producing a partial thrombosis and thereby exciting a trophoneurosis It is a fruitful source of investigation, and we must depend on the physiologist for some aid in its solution

Dr Robert A C Wollenberg, Detroit We must consider not only quality, but also quantity, i e, caloric values We know that most Americans eat too much meat, and considering the excess food in the light of a waste product, we can readily see that as such it may give rise to some of the phenomena which we describe at the present time as eczema Working along these lines, I have been cutting down the fats and starches, having in mind both quantity and quality Most of the children we see have been fed too much starch, and by carefully regulating their diet we have been able to get some very satisfactory results

Dr Walter J Heimann, New York In spite of the apparently divergent views expressed by the various speakers, I think we are not so very far apart Dr Sutton did not think it right to abandon the term eczema because it represented a group of cases the causes of which are unknown I agree with the latter portion of his remarks As a matter of fact, it does not make much difference whether we call it eczema or dermatitis of unknown origin, but for the sake of common sense, when we definitely know that a certain condition is a pathologic entity and when we know its etiology, let us call it a dermatitis of such or such an origin, or, if we do not know its origin, let us admit it frankly in our terminology, favoring dermatitis of undetermined causation to eczema

In regard to the statement made by Dr Biddle, I am inclined to agree with Dr Hazen's view I cannot conceive of a gastric ptosis causing eczema, although if there is intoxication associated with the intra-abdominal condition it may act as a predisposing cause Dr Burke spoke of twins receiving the same diet and living under similar conditions, one suffering from an acute vesicular eczema and the other entirely free from the disorder Of course, such instances are difficult to explain, it comes down to the individual reaction of the child to a general cause, or to some local precipitating cause

In connection with Dr Dyer's remarks, I think he agrees with my conception of eczema, for I said that I regarded it as a condition rather than a disease As an inevitable corollary it follows that it becomes the duty of the physician to try to determine the underlying cause of the condition It would be as appropriate to call colitis of unknown origin an eczema of the colon, as it is to call a dermatitis of unknown-origin eczema

Dr Charles J White, Boston I am perfectly in accord with what Dr Heimann said in regard to the etiology of these disorders the only point is the question of terminology We have so many causes of eczema that it renders this question a very difficult one, and before coming to any definite conclusion as to the nomenclature of these disorders I would like to emphasize the statement that it should be settled by an international board of dermatologists, not by a purely American board Dr Schamberg mentioned an interesting observation in the treatment of a case of poison ivy, and I think we should follow up that line of treatment It is in accord with the approved method of treating hay-fever and other affections, the object being to render the patients immune I would like to add one other possible factor in the production of dermatitis venenata, namely, the spruce tree My father spoke of it in his book merely as a possibility in connection with the use of spruce gum, but yesterday I saw a case of undoubted spruce tree poisoning In regard to diet in psoriasis, while most physicians have been restricting the protein intake, my associates have gone on with the idea that by excluding the starches in psoriasis the patients would improve and their results thus far have been very encouraging These patients have been put on the Allen dietary Dr Ketron spoke of the intradural method of testing proteins I have had very little experience with it, but the more one wounds the skin in these cases, the more likely one is to produce these reactions Dr Sweitzer spoke of leaving the diet in eczema to the pediatrist I am not in favor of that Only a few days ago I heard a pediatrist say that all cases of eczema in infants should be treated by the pediatrists As to the thyroid treatment of eczema, it might be beneficial because we know that the administration of thyroid extract increases the perspiration When Dr Hazen referred to eczema in children with discharging ears, I wondered whether he was not getting into the impetigo class, this is a larger group than we appreciate

Dr Frank Crozer Knowles, Philadelphia I have been extremely interested in this discussion and I think it is a great pity that some decision cannot be reached on the subject of eczema We had a discussion on the subject before this section in 1908 and before the American Dermatological Association four years ago, but it is still, apparently, as far from being settled as ever

Superstition and Medicine—Born in ignorance, nourished on superstition, clothed with mysterious rites and ceremonies, medicine has had a hard task to free itself from hereditary and environmental influences Attempts to break away from these adverse and retarding conditions has marked the highest efforts of the race During nearly every century since recorded history began, there have been some superior men, intelligent and far-seeing above the masses, who have contributed something to science Such were Hippocrates, Galen, Pare Servetus, Harvey and others whom we now delight to honor as contributors to knowledge and benefactors to the race—V C Vaughan M D *Science* Dec 8, 1916

SUMMARY OF THE PENNSYLVANIA STATE WORK IN POLIOMYELITIS

SAMUEL G. DIXON, M.D., LL.D., Sc.D.
Commissioner of Health of Pennsylvania
HARRISBURG, PA.

The geographic range of poliomyelitis, as I know it, includes England, beginning in 1838, Norway, Sweden, Denmark, Germany, and on this side of the Atlantic ranging from Cuba to northern Alaska. In the last twenty-two years, several epidemics have appeared in different sections of the United States.

The first to occur in Pennsylvania was in 1907, when 131 cases were reported by the grace of the physicians, the disease not being as yet reportable. Seven counties (Elk, Forest, Jefferson, Clarion, Venango, Warren and Lawrence) shared in this outbreak. The next year there was a similar outbreak, but altogether limited to Adams County, which had been untouched the year before. Here, as later, the mapping of the cases shows that the disease is not more likely to reappear in a center previously infected than it is to appear in some new center.

In 1909 our commonwealth suffered but slightly from poliomyelitis. The progress of the disease elsewhere led me to call the Advisory Board of the State Department of Health together. The result of our conference was the promulgation of a regulation placing poliomyelitis among the diseases reportable in Pennsylvania, thus our first comprehensive morbidity and mortality statistics began in 1910.

Up to July of that year, few cases were reported, but then came a rapid increase. In the month of August we had 275 cases, while September showed 378 cases. In October the fall began, the month bringing only 197 cases. In November there was a further fall to 95 cases, and during December it went down to 15 cases. This visitation totaled 1,112 cases in six months.

During the year 1910 there had occurred 269 deaths from this disease. From this eventful year for Pennsylvania, we looked forward to the next year with anxiety, yet 1911 passed away leaving a record of only 177 cases. Then came 1912 with 267 cases, while in 1913 there was a drop to 141 cases, and in 1914 to 113, but again in 1915 a rise to 162 cases.

The cases in these years were very much scattered throughout our territory of 45,000 square miles; the scattering, however, was not uniform. Whole counties were free, and we really have been unable to collect data to account for this distribution. In some of the cases, in remote, isolated homes in the mountains, there was not much else to hold responsible except the United States mails, if there was an independent micro-organism or a host in which the organism was spending part of the cycle of its life, or possibly a mere carrier to be transported from place to place.

The only real nestling notable in 1914 was in the southwestern section of Washington County, where we had thirty-two cases. The concentration of 1915 was in the northwest corner of the state, in and adjacent to the city of Erie, where there were about a hundred cases.

The year 1916 opened well, and as late as July 1 only twenty-two cases appeared in our statistics. This condition existed notwithstanding that Greater New York had an unprecedented number of cases during the latter part of June. So severe was this outbreak that, after a visit to New York, I had a full realization of the hysterical condition of the public over the sudden visitation of the disease with its high mortality.

Dr. John J. Mullowney, assistant chief medical inspector, was at once detailed to Brooklyn to live, and to observe and report everything connected with the epidemic, from the environment to the subjects, both alive and dead. A letter to Commissioner Emerson of New York brought Dr. Mullowney every facility to study the situation in a comprehensive way. His reports soon made plain that a considerable number were driven into the hospitals by the regulation calling for a quarantine of eight weeks.

In certain sections, however, in districts in which the disease prevailed, there was a tendency to stampede from what was called the "plague," and Pennsylvania was already being infected by those in the acute stage of poliomyelitis, as well as those who were infected and went down on their arrival in our commonwealth in one, two, three, four, five or six days.

While I do not intend going into the details of the work done in Brooklyn, I wish to mention the fact that we collected flies of different species from the infected rooms. These we ground up and soaked in a neutral salt solution, using the filtrate to inoculate monkeys, altogether with negative results.

With the facts already mentioned before me, and letters, telegrams and telephone calls from our people, asking and even demanding that some radical measure be taken to prevent the plague, raging in New York and New Jersey, from spreading into our state, and in my ignorance regarding the etiology of the disease and its methods of transmission, together with the information that along the railroads leading from the infected centers of New York and New Jersey the disease was rapidly increasing and showed a marked difference at these points over other places in the state, I immediately called the Advisory Board of the State Department of Health to consider the advisability of quarantining Pennsylvania against other states. The result was the unanimous carrying of a resolution to quarantine. This meant the guarding of a thousand miles of boundary line.

The department, which had been confronted by other emergencies, had no trouble in selecting the geographic points necessary to guard against various methods of travel from our sister states.

Men were equipped, instructed, and on duty within about forty-eight hours after the call for mobilization. The absolute quarantining of the sick was fixed for thirty days. These radical measures were, as I have said, demanded by the public, and our want of knowledge forbade our resisting the wish of those whom we represented, and whose health and lives had been entrusted to our care. The county medical inspectors, the health and special officers, numbering all together about a thousand men, were instructed to caution every one against the introduction of the disease among us and to report by wire to the central office of the department of health in Harrisburg every case discovered.

Officers were instructed to arrest on sight and quarantine suspects against coming in from other states. Circulars were distributed giving careful instructions how to nurse the sick. Medical men were requested to visit the patients in the townships, villages and smaller boroughs. Nurses had their instructions to visit the poor patients and have the homes cleansed and screened against insect life. All foodstuffs for children were ordered cooked, and the acutely sick were gently cared for until the active poison had played its part, and then nurses sought hospital beds for the crippled children that they might receive the proper treatment to restore mobility

All railroad coaches coming from infected districts were disinfected, all second-hand furniture coming from other states had to have a clean bill of health, as did all incoming children under the age of 16 years These measures kept thousands of sick and infected children out of our commonwealth, and I shall leave it to those present to determine what relation that had to our fortunate escape from a repetition of what happened in New York and New Jersey

You must remember that when this was done, and today, the medical men in charge of the epidemic in New York thoroughly believed that they had abundant proof of transmission of the disease by contact and by third persons With this belief so thoroughly grounded in those who were dealing with so many thousands of cases, there necessarily came up the question of the advisability of moving the educational machinery of this commonwealth on a short period to get it out of the danger zone, by taking in a portion of the safer season of the coming spring time The result was that the advisory board voted to postpone the opening of all schools until Sept 29, 1916 This moved the entire piece of educational machinery on in one solid block without interfering with its organization by breaking cogs out of the wheels here and there through the limiting of the postponement to those under 16 The people, however, lost sight of the organization of the schools and demanded that they be put on the same ground with moving picture shows and other places of amusement, where only children under 16 years of age were forbidden to congregate The first order, therefore, was rescinded and the general rule passed forbidding all children under 16 years of age to attend school until September 29 This left the organization of the school system entirely to the educators, and they wisely ruled to keep the schools closed to those of all ages, and in many cases later than September 29

The curve of the insect life runs closely parallel to the curve of poliomyelitis The disease is essentially a disease of warm weather The few exceptions are to be found very far north where the custom of living in huts in great filth and heat, and amid insect life is common The environment in the very northern and cold climates must be thoroughly understood by us before we conclude that it contradicts our belief that we are dealing with a disease of warm weather

When we turn to our statistics, the analysis of the mortality of poliomyelitis by sex and age adds little or nothing to our previous knowledge concerning the occurrence of the disease or the fatality Nearly a fifth (19 8 per cent) of all deaths occur under 1 year of age, a little more numerous (20 6 per cent) are the deaths between 1 and 2 years For each of the periods from 2 to 3 years and from 3 to 4 years the proportion of deaths is close to 13 per cent , and for the next year of life drops to somewhat over 8 per cent Taken together, the deaths under 5 years make up almost three quarters of all For the next quinquennial period, between 5 and 9 years, the percentage falls to nearly 15 (more exactly 14 7) For the next it is a little over 5 (5 3), and the same percentage remains for all patients over 15 An influence of nativity on the morbidity or mortality is nowhere evident

An exhaustive report, including all phases of the epidemic in Pennsylvania, will appear in our annual report to the governor

FURTHER OBSERVATIONS ON THE CONNELLAN-KING DIPLOCOCCUS THROAT INFECTIONS

THEIR SEQUELAE, WITH ESPECIAL REFERENCE TO ARTHRITIS *

JAMES JOSEPH KING, A B, M D
Attending Laryngologist to Hospital for Ruptured and Crippled Assistant Surgeon in Otology, New York Eye and Ear Infirmary
Chief of Clinic, Ear, Nose and Throat, Gouverneur Hospital
NEW YORK

The Connellan-King diplococcus is a small gram-negative organism It was first observed in my cases in the latter part of 1914, Connellan having found it a little earlier around the roots of teeth extracted by Hasbrouck and Palmer We have never found it outside of the mouth There, we have found it either in a tonsillar crypt or in some sinus in the tonsillar fossae after the tonsils have been removed Such cavities are partially anaerobic chambers Cultures have been made from the ear, the nasal chambers, and the nasal accessory sinuses, but so far they have all been negative for this micro-organism It grows slowly on most of the solid culture mediums, preferably on veal serum agar in the presence of moisture at about body temperature It is not pyogenic, but is a powerful toxin producer We believe it to be a local infection non-pus-producing, highly toxic, and noninfectious for the general blood stream Numerous blood cultures have been made from patients in whom this organism has been found, but so far all of them have been negative Likewise, many arthritic or so-called rheumatic joints in which this focal infection was believed to be the cause have been aspirated and cultured, with negative results In these respects it is analogous to the Klebs-Loeffler and tetanus bacilli

The clinical appearance of the throats in which this diplococcus has been found is characteristic, if this term is permissible from the comparatively small number of several hundred cases which have been observed by the author The color of the mucosa is purplish, distinctly darker than normal, and decidedly unhealthy in appearance The mucosa of the nose and nasopharynx is similar in appearance It looks lifeless and as if it had been the seat of disease for a long time The tonsils of the patients who have suffered from the more serious complications, as rheumatism, arthritis, nephritis, and cardiac lesions, have usually been rather small and submerged, with a brownish-yellow serum exuding from their crypts This serum has given such tonsils a distinctly moistened appearance This clinical observation coincides with the laboratory experience that this organism grows best in the presence of moisture Most cases in which this moistened appearance over the tonsils was found were seen by me months after the initial tonsillitis, and all of the patients consulted me because of an intractable arthritis, nephritis, or some such systemic condition that had resisted the ordinary treatment It has also been found in the large cryptic tonsils and in some pockets in the tonsillar fossae after the tonsils have been removed

We believe that the absorption of chemical toxins from this micro-organism is capable of producing serious pathologic lesions in the nervous system, in

* Read before the Section on Laryngology Otology and Rhinology at the Sixty Seventh Annual Session of the American Medical Association, Detroit, June 1916

the heart, kidneys, joints, muscles, glands, blood and respiratory tract These symptoms or sequelae may be so serious that life itself is endangered All of these complications have been observed in my clinical experience with this diplococcus Improvement and cure have followed the removal of this infection in numerous patients who had previously resorted to every known means for the alleviation of their symptoms, whether it was an obstinate asthma, arthritis, endocarditis, myocarditis, or nephritis By this it is not meant that every patient in whom this organism has been found has been cured, but that we have a record of at least one such case in each type in which the eradication of the focal infection by this organism has stopped all symptoms The typical clinical history of such cases is as follows

The patient had a tonsillitis of greater or less severity and, sometimes, even no discomfort was felt in the tonsils, but only an infection in the nose and throat was noticed Within a few days or a few weeks, some other symptom developed The tonsillitis or infection of the upper respiratory tract may have been so slight that it was entirely forgotten by the time the complication developed If the complication was arthritis, or the so-called rheumatism, it usually developed shortly after the initial tonsillitis As a rule, the severer the attack of tonsillitis the sooner have the complications manifested themselves

At the present time we have under treatment a patient who had a severe attack of tonsillitis three years ago, with a temperature running from 101 to 103 F Within two or three days from the onset of the tonsillitis, she developed a myocarditis She has not been out of bed since that initial attack of tonsillitis She has had a temperature of over 100 F and a pulse rate of from 110 to 120 every day for the last three years Her blood pressure is now about 105 mm of mercury She is helpless, not being able to sit up in bed even for her nourishment She is sometimes so weak that she cannot hold up a newspaper before her

The first patient in whom this micro-organism was found, associated with much contamination, had a severe chill, followed by an elevation of temperature to 105 6 F When his urine was examined the next day, it had albumin and hyaline and granular casts The nephritis and extreme toxemia were his only complications

Our observation has been that if the tonsillitis is severe, the complications generally ensue quickly, if mild, they develop later, in from one to eight weeks In our own patients, who have been seen during the initial attack of tonsillitis and treated with vaccines, no complications have developed after the treatment was commenced The complications have developed in all cases without a chill at the onset As just stated, one patient with this infection, associated with a mixed infection of the accessory sinuses and tonsils, had a severe chill at the outset This, however, has been the only patient who had such a chill

The prognosis of acute tonsillitis in which this organism is believed to be the causative factor varies greatly with the treatment All of my patients with acute forms of the disease who have been treated with autogenous vaccines have been relieved of all symptoms, and no complications or sequelae, such as arthritis and rheumatism, have developed Patients who have been treated in this manner made unusually rapid recoveries from tonsillitis In some of the acute cases there were nephritis and arthritis, but these also have been cleared up promptly by the treatment

On the other hand, I have seen many patients in consultation, long after the initial tonsillitis, who called on me because of some obstinate complication, as arthritis or some cardiac conditions, and this organism has been found in the tonsils as long as five years after the initial sore throat from which the trouble dated Many such patients have been relieved by the administration of autogenous vaccine and enucleation of the tonsils, as the case reports will show

We are therefore led to believe that some of these complications might have been averted by the prompt administration of the autogenous vaccine during the acute tonsillitis The pain and swelling in arthritis or rheumatic joints in a considerable number of cases of from one to five years' duration have been relieved by this treatment In some cases in which great changes or bony ankylosis and exostoses have taken place in the joints, the treatment has stopped all evidence of activity, as pain, redness, and swelling of the soft tissues, leaving only the deformity In a group of cases in which, in addition to the joint symptoms, there were cardiac and renal changes, great improvement in these conditions has taken place

The symptoms, complications, and sequelae of this infection can best be described by reciting cases which illustrate types These will follow after a few words on the treatment in a general way

Treatment—This consists in eliminating the infection So far as we know at the present time, the focus is situated within the mouth, either at the root of a tooth or in a crypt of the tonsillar fossae A culture is taken from the patient, and if it proves positive an autogenous vaccine is made It is prepared so that 1 c c represents 200 millions of the diplococci The vaccine is given three times a week until all activity of the infection has ceased, and then if the focus is in the tonsils, they are enucleated, unless there is some contraindication Patients whose teeth need attention are referred to a competent dentist for appropriate treatment

We believe that the administration of the autogenous vaccine not only stops the activity of the organism by overcoming the effect of the absorption of its toxins, but that it renders tonsillectomy a safer and more satisfactory operation Frequently after a tonsillectomy there is a low-grade sepsis, which is not only annoying to the surgeon, but also may endanger the patient's life For instance, we have seen several patients whose tonsils were enucleated for the relief of rheumatic pains immediately have a subacute exacerbation of the attack, which continued indefinitely, and the disease for the relief of which the tonsils were removed was not helped My experience with the autogenous vaccine treatment of these patients leads me to believe that much of the trouble can be averted by their use as a preliminary step to the operation

As there has been no precedent in the dosage of this vaccine, we have had to feel our way as we went along The dosage of even well-known micro-organisms has not been definitely established As first, 200 millions of the diplococci were given subcutaneously every four to seven days, and gradually increased according to the indications to be met and the reactions obtained For some time now, 200 millions have been given three times a week The dosage has varied according to the individual to be treated In the aged and debilitated and in young children the initial dose has been much smaller and was gradually increased according to the reactions If a severe reaction is produced in any one case, the dosage is reduced, and vice versa The reactions manifest themselves usually by an elevation of temperature of one or two degrees, local pain and redness, slight pains over the body, and frequently by a slight exacerbation of symptoms As a rule, these reactions become less and less until none are produced In some cases the organism has persisted in the tonsil even after all symptoms had disappeared and the vaccine had been given until no reactions were produced The reaction varies greatly with different individuals, and some patients complain of more pain in one arm than in the other

In previous communications[1] I have reported a number of cases of arthritis, nephritis, anemia, endocarditis, and myocarditis in which the Connellan-King diplococcus was the causative factor These patients have all been treated within the last two years, and it is now my purpose to add a further report on these cases

REPORT OF CASES

The first patient who was reported in the preliminary report was treated in November, 1914 He had at that time acute tonsillitis and nephritis All symptoms disappeared under the vaccine treatment He had a recurrence of tonsillitis in March, 1915 He received more vaccine, but his tonsils were not enucleated He made a rapid recovery from the tonsillitis At the present time he is well and has had no recurrence of the nephritis

Another patient mentioned in the preliminary report, and reported again later, consulted me in December, 1914 for the relief of a severe arthritis following an attack of tonsillitis ten months previously She was relieved of all active symptoms by seven injections of the autogenous vaccine In March 1915, she returned to me for a tonsillectomy At that time cultures made from the crypts of the tonsils again showed Connellan-King diplococci She had, however no symptoms either of tonsillitis or in the joints The tonsils were enucleated and a few doses of vaccine given, but there were no reactions She made an uneventful recovery from the tonsillectomy and has had no further activity in the joints Her right knee is ankylosed, but she has no pains and can walk without a crutch or stick, whereas when she first consulted me she had great pain and had to use a crutch in walking

Miss E S, who was reported as Case 4 in a previous communication, is perfectly well at the present time She first consulted me about a year ago for the relief of multiple arthritis and endocarditis following a tonsillitis five years before During the past five years in spite of treatment, the arthritis was progressive and this coupled with her cardiac condition, incapacitated her for work During the summer of 1915 she received vaccine treatment and her tonsils were enucleated The conditions were relieved promptly At the present time she is well, although her joints still show a slight deformity Her heart has a slight murmur, but it is so much better that the damage can be detected only by a very careful examination Her general condition has improved greatly, and she has been attending to her usual duties for the last six or eight months

The following new case is striking, and is typical of a considerable number in my private records

Miss D C aged 21, was seen by me in consultation April 2, 1916 Twelve weeks previously she had had a severe tonsillitis A few days later she developed rheumatism in nearly all the joints of her body The tonsillitis soon disappeared under the usual treatment During these twelve weeks she was confined to bed under the constant care of her family physician, nurses, and various consultants Her range of temperature was from 101 to 104 F When I entered her room her condition inspired me with the greatest pity She was lying there in bed with her arms folded over her chest in great pain, and she said, "Don't touch me" The fingers, elbows, knees, and toes of both sides were swollen, red, and exquisitely painful Her heart action was very rapid, and while no murmur could be detected at that time, one was expected to appear at any examination She had been treated with all the usual remedies without effect, and opiates were given to control the pain

A culture was made from the crypts of her tonsils It showed a pure culture of the Connellan-King diplococcus An autogenous vaccine was prepared and was given by her physician three times a week All other treatment was stopped when the administration of the vaccine was commenced

As a result the temperature came down within a few days and the heart action improved remarkably and rapidly The pain and swelling in the joints disappeared with equal rapidity About three weeks from the time the culture was taken from her throat I saw her again and she was in splendid condition She was up and going about as usual, had no pain in the joints, and felt splendidly It was most gratifying to see her so well and happy

If space permitted, a great many more cases could be reported, but these are sufficient to illustrate types

CONCLUSIONS

A study of these cases enables us to reach the following conclusions

1 The frequent presence of the Connellan-King diplococcus in the crypts of the tonsils or at the roots of the teeth in arthritic patients suggests that it may be specific, and that a simple tonsillitis may be followed by very serious complications, due to an absorption of chemical toxins

2 The danger of a general sepsis following tonsillectomy might be eliminated if a culture were taken from each patient

3 If the focus of infection in arthritis exists in the tonsil, the treatment should consist in the injection of an autogenous vaccine until all infection is cleared up and then the tonsils should be removed by enucleation

4 The blood changes in the Connellan-King diplococcus infections seem to be a simple anemia and, in a few cases, a slight increase in the eosinophils from 4 to 6 per cent

5 In some cases symptoms other than those for which treatment was instituted have disappeared For instance, in one patient with arthritis and marked ethmoiditis the culture was obtained from the throat Within two weeks the ethmoiditis had cleared up, while the arthritis was only slightly relieved Another patient with serious gastric disturbance, who had found it necessary to remain on a strict diet, was able to eat almost anything after she had received the treatment with the autogenous vaccine

40 East Forty-First Street

ABSTRACT OF DISCUSSION

Dr John J Connellan, New York About two years ago, Drs Hasbrouck and Palmer of New York asked me to examine their extracted teeth and ascertain if *Endamoeba buccalis* was present We were unable to find the endameba in any case As several of the cases showed abscesses, cultures were made The organisms found were the *Streptococcus viridans*, from the apex of the tooth and *S hemolyticus* from abscesses We also found in some of the cases a gram-negative diplococcus which I had not seen before, nor was there anything in literature calling attention to this organism I then asked Dr King if he would make cultures from other parts of the throat and mouth The result of such work showed this organism present in the crypts of the tonsils and around the teeth

[1] King Abstract of a Preliminary Report on the Connellan King Diplococcus Infections of the Throat Laryngoscope 1915 25, 229 The Connellan King Diplococcus Infections of the Throat with Especial Reference to Rheumatism Med Rec New York 1915 88, 958

[2] Second reference of Footnote 1

Since that time we have found it in numerous cases at the apex of extracted teeth, some of which were decayed and others in good condition, but in which the roentgenogram showed abscess formation The organism is a typical bean-shaped gram-negative diplococcus It is slightly smaller than the gonococcus when it has attained its maximum growth on its best growing medium I have been unable to find this organism outside the mouth and throat Its best growing medium is human blood agar with a little veal serum added The main point in its growth is the reaction of the medium On not more than 0 2 per cent acid will the organism grow In preparing the medium it is absolutely necessary to use the titration method Litmus paper should never be depended on It does not produce acid as produced by other gram-negative diplococci, described by Dunham, from the nose and throat In using the Hiss sugar serums, we get no reaction except coagulation of albumin, showing that it is not a gas producer, which brings to mind why when found in these apparently good teeth with abscess formation at the apex there was no history of pain by the patient The organism is best grown at a temperature from 39 to 40 C It has a characteristic appearance on the medium, colony being a light, dull yellowish-brown with a rounded contour The size of the colonies is approximately that of the *Staphylococcus albus* Dunham, Van Lingelsheim and Elser and others have reported several gram-negative organisms found in the mouth and other parts of the body, but this organism does not compare with any that these investigators have reported As to the animal injection, intraperitoneal injections of guinea-pigs, dogs and white mice produced no symptoms Two cubic centimeters of sterile salt solution (a cubic centimeter containing approximately 100,000,000), were injected into the marginal vein of a rabbit producing death in four days The organism was recovered in the heart Complement fixation experiments are now being worked out by an investigator in New York City

Dr Emil Mayer, New York My own experience does not entirely tally with that of the speaker in that I cannot report anything like such a percentage of cures I had one instance which was very interesting a nurse in the Training School in Mount Sinai Hospital, who had been suffering for more than a year with a temperature ranging daily from 101 to 104 F, without any known cause She came to me because her tonsils had been troubling her for some time and she wanted to have them removed, but I felt that that was not the thing to do in connection with her condition so far as this temperature was concerned I then made a test and sent it to Dr Connellan and he reported very promptly that it contained the Connellan-King diplococcus and sent me some vaccine The vaccine was used and to my delight and surprise she lost her high temperature This lasted but five days At the end of that time the temperature went bounding on as before The second case was that of a young woman who came to me complaining of a mastoid pain, but further examination revealed that she was suffering from a general periostitis We found the same diplococcus-bacillus, and the result of the vaccine was all that could be desired She got entirely well The third patient was the most interesting who has come to me, and I am anxiously awaiting the results A man complained of a rather slight pain in his throat There was nothing much to be seen there I looked on it as a little local infection, and made application of the usual remedies With that he seemed to get entirely well, but in three weeks he came again with the same pain in the same place I suggested that I take a culture, and the result was a most beautiful colony of these diplococci-bacilli The question is, Is this one of the cases in which we probably have a forerunner of an arthritis, and shall we advise the man, in spite of the fact that he has had apparently few symptoms, to go through the vaccine treatment or shall we wait and see? If this man should decide not to take that treatment and subsequently should develop rather a severe arthritis, I think we should be very much in the position of demonstrating that this was undoubtedly the causing factor in his arthritis

Dr Virgil P Gibney, New York I had been looking for a long time on the *Streptococcus viridans* in the roots of teeth or about the alveolar processes as a cause of many of the arthritides On still further investigation I found that the Connellan-King diplococcus was a possible cause of arthritis We have, therefore, two causes of infection in the buccal cavity, namely *Streptococcus viridans* and the Connellan King diplococcus One of the cases shown by Dr King I recall very well It was a case of ostearthritis of the hip I found restricted movements and history of slight trauma Having acquired the habit of looking for the cause in the buccal cavity, I found some suspicious teeth, and had a roentgenogram made which confirmed my suspicions I also found that the tonsils needed attention Dr King and a dentist took the patient in charge, and he made a fair recovery He has still a little lameness, but he suffers no pain, and the outlook is very hopeful that he will be free from lameness and deformity Confirming what the doctor has said about the progress of the patients under the use of vaccines and the removal of the focus, I wish to say that the cure of an ostearthritis is not always phenomenal Recovery does not take place in a short time You will recall that this disease is accompanied by osteophytes about the margin of the joints making movement painful and it requires some little time to get rid of these deposits

Dr Isaac H Jones, Philadelphia Dr W P Conway of Atlantic City had frequent attacks of arthritis for eight years He became progressively worse and developed a severe endocarditis and such a marked nephritis that at one time he had complete suppression of urine His loss of weight was marked Dr King found his diplococcus in the tonsils, gave an autogenous vaccine and soon after removed the tonsils Dr Conway is now in perfect health It seems to me that we should attribute the cure to the removal of the tonsils rather than to the vaccine, although it is important to note that the vaccine produced a marked improvement even before the tonsils were removed

Dr James J King, New York The patient Dr Mayer spoke of as having the high temperature was afterward found to have a tuberculous peritonitis

Dr George F Cott, Buffalo Would you get the same results in removing the tonsils after using the vaccine?

Dr King That is a very important point Occasionally after a tonsillectomy a low-grade infection may continue and even endanger the patient's life By giving the vaccine before you operate you clear up that field and operate in a clean field and in that way avoid this danger To be sure, we do not see these infections very often, but they come sufficiently often for us to give the vaccine, clear up that infection, and then operate in the interval, just as we do in appendicitis By this means the operation is safer, and it is possible that all of these cases might be prevented if we would do this I have had no infection following my tonsillectomies in cases in which I have given the vaccine before the operation I have sometimes found the infection still in the tonsil, but it was inactive I had one patient in whom the culture was taken for the second time about a year after the vaccine was given We found the infection in the tonsil again, but there was no activity, whereas when I first saw her she had a great deal of arthritic pain and had to walk with a crutch The vaccine stopped the activity, stopped the pain, the arthritis disappeared, she got rid of the crutch and was perfectly well when she came back to have her tonsils removed

---

Bartholin's Tercentennial—October 20 was the three hundredth anniversary of the birth of Thomas Bartholin at Copenhagen After studying at all the universities of Europe except the German, which at that time were desolated by the Thirty Years' War, he settled in Copenhagen and in 1647 became professor of anatomy in the university He changed to the chair of general medicine at the age of 40, and published a number of works on the history of anatomy and medicine besides reports of his own researches He never cared to practice medicine, and fled from Copenhagen when the plague swept down on it, but his fame placed Denmark in the lead in science during his career His works are in Latin, and his name is Latinized, his real patronymic having been Bertelsen The University of Copenhagen had a festival gathering, October 20, in honor of his tercentennial, Professor Maar delivering the memorial address

MEDICAL SUPERVISION OF STREET RAILWAY EMPLOYEES *

CHARLES H LEMON, M D

Fellow of the American College of Surgeons, Chief Surgeon, The Milwaukee Electric Railway and Light Company

MILWAUKEE, WIS

The highly complex character of modern business, and by this I mean big business, demands a physical endowment that is commensurate with the high intellectual endowment which has made possible the great industrial establishments that control the business of the world Such an organization requires diversified talent and as its growth is dependent on continuous existence, it is necessary not only that the general health shall be conserved, but that by continuous medical supervision, following elimination of defectives by preliminary examination before employment, the places of those whom disease or advancing age render inefficient shall be from time to time filled by trained subordinates To meet these conditions and to preserve the traditions of the business is the problem that every large corporation is confronted with

The aim of the employer is obviously to select from among those who apply a number who will give promise of developing after employment The applicant, excepting in special cases, is raw material that must be molded into efficiency, and because of the specialization which is the very essence of modern business, every man is not found qualified

Modern business differs from that of a quarter of a century ago in many particulars Under the old order, the man was not considered an entity He was merely a hand He came and went as the needs of the business demanded His relation to his employer was a negative one His joy and his sorrow were shared by no one and the tenure of his position was dependent largely on the whim of his immediate foreman When he became sick his place was filled by another He was dependent on the cheapest, unskilled medical services for his recovery and during his disability no provision was made for his immediate financial needs When he left the shop he lost all contact with the organization which employed him

This deplorable condition undoubtedly was the result of the sudden expansion of business in the decade following the Civil War The small shop gave way to the factory and every industry took on a corporate character The "corporation was without a soul," and in the keen competition which necessarily followed the man was lost sight of He was merely a hand at a machine and, by comparison, far less important than the machine itself

In the mad rush to accumulate fortunes the managerial mind was centered on the results of the year's work only and the sum of human misery that was added to the account found no place on the balance sheet Not only was business unmindful of the welfare of those whose life blood was poured out to create it, but it was also blind to the thought that the very essence of sound economic management was dependent on the welfare of the individual unit, and that unless that individual is physically and mentally alert, economic waste occurs

The railroads were among the first to learn the value of taking a human interest in their employees While the character of the occupation was necessarily hazardous in comparison with many other industries, it was by no means in a class by itself in this respect

In the development of modern business with its very humane interest in the welfare of its employees, we find the railroads many years in advance of the other industries Until within a few years no voluntary medical services were offered injured employees in our great American industrial establishments The first aid rendered was given grudgingly and in most instances was rendered by a city-maintained hospital without expense to the manufacturer The change of policy which has occurred is not altogether due to any softening of the heart, but rather to a combination of public sentiment expressed in the concrete form of industrial injury compensation laws and to more enlightened management, the result of education along public health lines by our government

How different from the very beginning of their corporate existence has been the practice of the railroads in taking care of their wounded employees They have recognized for more than a half century that injuries incident to operation were properly chargeable to the cost of operation This thought is the basis of all welfare work, as it provides the capital which is essential to making welfare work practical rather than sentimental

Railroad surgeons have been identified in the public mind with the operation of railroads ever since railroading began In no other industry have they been deemed so essential The general supervision of the health of the employees, which follows as a corollary to the general employment of surgeons throughout a large railway system, is a fact of importance that should not be lost sight of The friendly suggestion by the doctor to the man who is in failing health is the human touch of the corporation

Again, the general efficiency of railway employees is a matter of common knowledge The underlying fact of this efficiency is that railway men are picked men No one goes to work in the operating department of a railway until he has been examined by the company doctor

Here then is the first important lesson the industries must learn, that any kind of efficiency that is not based on a sound, alert, well-balanced human machine is bound to be economically disastrous The industries are just beginning to learn that the human mind is a wondrously complex mechanism and that machines cannot be adapted to men, but men must be sought out, by a process of elimination, who can adapt themselves to the machine They are learning the lesson also that physical fitness is a prerequisite to efficiency The matter of maintaining the average health of employees by physical examination, therefore, before and during employment, is in conformity with the advancement of modern medicine, which is distinctly preventive In recruiting for the army and navy, how careful at all times has the government been in its selection of material No matter how great the emergency, the culls are left behind With our thoughts centered at this time on preparedness, it is gratifying to the managements of the great railways to know that the government recognizes, in the well-trained, selected and disciplined men who make up the vast army of railway employees, an auxiliary effective arm for the military service

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty Seventh Annual Session of the American Medical Association Detroit June, 1916

* This article and the one by Dr Smith which follows are part of a symposium on Industrial Medicine.' The first two articles by Drs Mock and Clark appeared last week

The relation of human impairment to accidents is well known They bear to each other the relation of cause and effect It is therefore quite as important to save a man by a process of elimination from himself as it is to safeguard fellow employees who will be put to undue hazard by reason of his infirmities The best safeguard against accidents is an alert mind in a virile body, on the other hand, the sure preliminary to accidents is an exhausted, devitalized human machine

In a diversified business the man seeking employment will represent every possible variety of human activity, from the illiterate foreigner who applies as a laborer to the highly trained engineer and accountant For the particular department or bureau that is applied to, certain characteristics of mind and body are required The applicant himself, by a process of elimination, places himself in a particular group when he applies to a specific department for employment It is true he may be mistaken in his estimate of his ability, but we must at least recognize that he has specialized in his own case This type of man to my mind is highly desirable, because in all but the lowest types of labor, where the bare necessities of life force the man into activity, we have the elementary idea of fitness expressed

The necessity of a preliminary examination of applicants for employment would seem to admit of no serious debate Before the Milwaukee Electric Railway & Light Co organized the Employees' Mutual Benefit Association no one was examined prior to employment excepting those who were to be employed in the operating department of the company The advantage of a medical examination was obvious

Had it not been for the industrial depression following the outbreak of the European war, it is altogether probable that these results would not have been attained As men, one after the other, left their positions, the positions were not refilled, and the working force was reduced to the minimum For months little change occurred in the personnel and a marked change occurred in the accident experience in every department An improvement was also noted in the general health of the men

Some idea of the extent of the accident reduction, involving not only accidents in the industry itself, but accidents to the public who rode on the cars or were brought in contact with them, may be had from the statement that in the year 1915 the cost for injuries and damages was nearly $100,000 less than in the preceding year In the year 1915, also, the average sickness per man per year was reduced from eight days in 1913 to a little more than four days per man per year

We have in these combined results the summary of two factors (1) a campaign of education, both within and without the company for the prevention of accidents and (2) the result of a careful preliminary examination of employees, as well as a maintained high level of health incident to a very close supervision of the general health, by dividing the men employed into groups, in which they could be daily observed and in which the relief from the lesser ills which lead to greater could be had without delay It may be argued that being a medical man I am looking through prejudiced spectacles and claim too much as the result of medical supervision On account of the difficulty of obtaining labor at any price and almost under any conditions at the opening of the work this spring, the company was forced to abandon temporarily its examination in common laborers Great stress had been brought on me as chief surgeon to relax the requirements in nearly every department The management, however, took the position that such excellent results had been obtained during the past two years that unless some unforeseen contingency arose which might temporarily force a further abandonment of examination, nothing should be done to relax the rule which had given us such a good showing in the year 1915

Preventive medicine has achieved a victory in convincing big business that medical science is an economic factor in conserving the health of those who are essential to the advancement of the business Any factor which promotes efficiency by maintaining a high level of general health will interest the business men who are at the head of modern industrial establishments, and the more broad-minded and far-seeing these managers are, the sooner will they come to recognize the importance of medical supervision of employees

I have been surprised at the results that have been obtained in our own company The action of the management in insisting on the continuance of the pre-employment medical examination at a time of great industrial activity, when men are at a premium, is to my mind an excellent endorsement of the things we are here striving to obtain We are not theorizing in this matter, and when we can show results which make for industrial efficiency, we have taken the first step toward raising the general health of the community at large How short sighted a business management must be which ignores facts like these The more difficult it becomes to obtain employment, the more desirable that employment will become The military establishment is founded on the theory of life employment of the physically fit for its officers Modern business must follow this example, and the railroads particularly are interested in the matter of training men to fill the positions higher up as these become vacant There are traditions in every business and every successful business has been true to its traditions We know the percentage of those who succumb after careful physical examination We therefore must meet the man who seeks employment with obstacles which put him to a severe test, and if he survives the test, we may look for returns on our investment in his employment

We have seen that the employer will have to look about him to find the man suitable for the work in hand We must assume that the head of a department has the best interest of his company at heart and will not employ a man who is manifestly incompetent or who by reason of manifest physical defects would cause undue hazard When labor is scarce and the management, because of the necessities of the business, holds the head of the department to an average, rather than to a high rate of pay, the temptation will become great to employ men who are physically below the average

We recognize that certain trades produce characteristic injuries to many who follow them and that in men working at a bench these deformities do not create a hazard nor do they lessen the efficiency of the individual I would not think that such men would be employed when others who are perfectly sound are available, excepting in case the man who had lost a portion of one or more fingers was a man highly skilled at his trade Among laborers, who for the most part are temporary employees, the loss of portions of the fingers, providing it did not interfere with the normal grip, could well be overlooked

In a large business undue influence is frequently brought to bear to obtain employment in going companies for relatives who frequently are derelicts A disposition to yield to these demands can bring forth nothing good They are not emergencies, as far as the company is concerned, and they should be employed only after the most careful investigation into their fitness

As an examiner of trainmen for many years I can bear testimony to the fact that men who have for a number of years worked for industrial companies and who from time to time have been laid off for lack of work have entered the service of our company with unbounded enthusiasm, because they were obtaining employment which would give them a fixed income In a going concern like ours this fact should not be lost sight of, for the man we are employing, it is fair to state, is receiving a greater benefit than we are obtaining in his employment This fact, in itself, by relieving the employee of worry about the support of his family, enables him to concentrate his mind on his work I know of no greater incentive to good and efficient service than the thought that your employment is permanent and that the officers of the company are interested in your personal welfare

That every business must make an analysis of its own conditions is illustrated by the following experience In the year 1914 in an effort to discover the cause of a loss in efficiency of trainmen, amounting to 15 per cent, because of alleged sickness, our company decided to place a medical man for a period varying from one half to one hour each day, excepting Sundays, in each of our car stations and large car shops It was hoped that by giving aid to men who reported sick, before the sickness became disabling, this percentage of lost efficiency might be materially reduced It was suspected also that there was a definite amount of malingering on the part of the younger employees, whose desire to get rid of their last pay check was an obsession with them At the same time it was feared that the men might feel that a censorship was being maintained, and before putting this into effect, the matter was submitted to the directors of the Employees' Mutual Benefit Association, who represented the trainmen and other workmen To our gratification it was received as intended, and immediately put into effect The beneficial effect of this personal contact between medical man and the employee was immediately noted

For the month of January, 1916, two years after the inauguration of this system in one of our largest stations with over 600 men, there were but 623 days of sickness I mention the month of January, 1916, because throughout the eastern portion of the United States in that month, as well as in December, 1915, we suffered from a severe epidemic of the grip Notwithstanding this, with thousands of cases in our city, only 623 days were lost through illness during the month by more than 600 men But we must not claim for medical supervision only the general good health of our trainmen The company has cooperated with us in the matter of better cleaning and ventilating of street-cars, the building of sanitary car stations and by increasing the average wages of its employees with the increase in the growth of the business This has enabled employees to live at home under far more sanitary and healthful conditions than were brought to my attention twenty years ago, when I first became associated with the company

In the general office building, where approximately 400 clerks and other employees are housed, spring water only is used, which is brought nearly twenty miles to the city from a spring owned and developed by the company in the famous Waukesha district

The more regular hours of duty brought about by a more intelligent study of schedules is also a large factor in health conservation, because these men work in the most inclement weather and under conditions frequently in which exposure to the elements becomes a positive menace

That any city railway employing a staff of surgeons can undertake large welfare activities for the betterment of the health of its employees, their wives and dependents at comparatively little expense is illustrated by the experience of the Milwaukee Electric Railway & Light Co during four years With a contribution of $6 per year per man for each member of the association, and an additional $6 per man per year contributed by the company itself, together with the voluntary services without pay of the officers and other employees of the company, in addition to paying $1 per day for 100 days of continuous sickness, and 50 cents per day thereafter for a second 100 days, and $300 for a death, the giving of all medical and surgical services free to its members, including the services of a welfare secretary and a visiting nurse, in a short period of four years the Employees Mutual Benefit Association has accumulated a reserve fund amounting to approximately $50,000

So great has been the reduction in the average days' disability per man per year, and so great is the confidence of the management that this ratio can and will be preserved by the effective organizations which we have, that in January, 1916, without further expense to the members of the Employees' Mutual Benefit Association the company increased its medical service so as to include the wives and dependents of all members This necessitated the increase of the medical force and added largely to the expense for medical supervision, but in a most comprehensive manner it has endeavored to relieve the financial burden of its employees for medical and surgical services to their dependents, and by the making of these services available it has encouraged health conservation, by enabling the employee to call the doctor with the early manifestations of disease, when for financial reasons he would otherwise delay the call

The importance of this service I have but to suggest to this gathering Would space permit, a summary of the work performed during the first five months of this year would be most interesting I hope, however, at some future time when the work is more advanced to present an analysis of this work, of which we have a complete record It embraces the entire field of medicine and surgery and offers to those who are members of our surgical and medical organization a most interesting and instructive clinic There are exceptions to all rules and we note an exception to this medical service We do not do obstetrics and we do not treat the eye and ear We do, however, remove tonsils and adenoids

May I close this paper with a brief statement of the activities which as a corollary have come as a result of the organization of an Employees' Mutual Benefit Association, which has served as a melting pot into which have been poured the burdens of the employer as well as those of the employee, and out of which has come a record of health, happiness and prosperity which I do not hesitate to say, because I have looked into the matter thoroughly, will not be found in any other similar or large corporation in any part of our country?

We have a savings and loan association, additional life insurance, sick and accident insurance, a provident loan fund, where money can be had without interest, old age pensions, a women's auxiliary, indoor baseball, bowling, outdoor baseball, a band, a dramatic club, and all the auxiliaries which go to make up healthful recreation and promote happiness

It is the combined result of these various activities, which cements together the body of employees and holds them to their work, improving the condition of their health and teaching them the wise practice of economy

In the words of our welfare secretary

> In the work of caring for those who are sick the women's auxiliary which was organized during the past year, has proved extremely beneficial and is unique There are innumerable cases in which the regular benefit provided by the Employees' Mutual Benefit Association does not completely meet the requirements of the case When the mother of a family of small children is sick for a long period of time, it is a great relief to have the friendly services of members of the women's auxiliary, who step in and perform some of the household duties, taking from the mind of the patient much worry, and making the conditions most favorable for a speedy recovery In cases in which a mother must be removed to a hospital the care of small children becomes imperative, and if there is no relative who can step in to perform this duty, members of the women's auxiliary have very generously assisted to solve the problem This organization has also provided baby outfits for needy infants, when proper provision has not been made for the new arrival in the way of clothing and a number of poor families have been provided with Christmas cheer through this same organization
>
> Beginning in 1912 with the Employees' Mutual Benefit Association, which was organized primarily to create, manage and distribute a fund to provide free medical assistance for members unable to work because of sickness or because of accident, when not within and subject to the provisions of the Workmen's Compensation Act, the association has become a most efficient machine for conserving the health of those who work for this company, as well as by caring for their dependents whenever disease or accident necessitates medical or surgical aid We have seen this association expand far beyond the limitation contemplated as its field of operation when it was first organized Its greatest field of usefulness has not been the payment of sick benefits or death claims, but rather the conservation of the health of its members Through the opening of doctors' offices at places of employment, it has been possible to reduce the amount of time lost on account of sickness by fully 40 per cent, making a total annual saving of something more than 10,000 work days

Once a year, divided into two days of fun and recreation, 12,000 people, including employees, their wives and families have a picnic with a 20-mile trolley ride

The electric industry today is attracting to itself a better and more educated class of men, because the requirements of the business with its diversified interests demands a high degree of intelligence In a large corporation it is possible to have a feeling of intimate relationship, and the medical man perhaps above all others comes closer to bringing about this happy condition We feel in Milwaukee that few corporations will be found whose gifts to their employees in the matter of health are so comprehensive and far reaching

The very best that industrial life holds for any individual under ideal conditions is employment by which he may earn a living for himself and his family, in work that is at once congenial to himself and useful to his fellow men, and that gives him an opportunity to rise to higher places of responsibility, that provides him an income sufficient to permit of his putting aside a surplus large enough to care for him, both in sickness and in old age, and that permits his work to be wholesomely interspersed with periods of rest and recreation

---

BAD TEETH AND THEIR EFFECT ON THE LABORING MAN'S EFFICIENCY *

CARL E SMITH, D D S
AKRON, OHIO

Efficiency from a health standpoint is difficult to determine We know, for instance, that if the water supply of a community is pure, the community is saved economic loss from typhoid, the same can be said of the milk supply and of all the precautions necessary to keep a community in health

This is true from a dental standpoint If we teach a large body of people mouth hygiene we cannot say how much better their health will be, or how much we have saved them through the prevention of mouth and systemic diseases

In the past sixteen months I have made 30,000 mouth examinations, for 17,000 Americans and 13,000 foreigners Of this number, 96 per cent are in need of dental service, only 4 per cent have clean, healthy mouths, 9 per cent are without cavities and could be made healthy by a thorough cleaning, the balance have all the pathologic conditions known to dentistry, pyorrhea pockets, decayed and abscessed teeth, mucous plaques with all the virulent bacteria ready to cause disease the moment there is a lowering of the resistance The danger from a dirty mouth is quite generally recognized, practically all contagious diseases being transmitted by the nose or mouth and the mouth is the more dangerous of the two In a mouth free from caries, but with deposits of calculi and mucous plaques, gingivitis develops, and because the gums are painful and bleed the man gives up mastication, and food passes to the stomach carrying pathogenic organisms The stomach cannot do double duty and in time disease results And so by teaching oral hygiene to the laboring man and he in turn carrying the idea to his family, we are cutting down disease, not only in the factory, but in the community

Suppose an epidemic of scarlet fever breaks out in a city The health authorities find these cases along a certain milk route, and they look up the farms on which this milk is produced and find a case of scarlet fever I have never heard a satisfactory explanation of how that first case started, apparently spontaneously Could it not be a case of lowered vital resistance from some cause and a dirty mouth, in which the germs of scarlet fever predominate? Whether this be true or not, the teaching of oral hygiene to the laboring man is important if it does nothing more than prevent caries, pyorrhea, and other mouth diseases

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty Seventh Annual Session of the American Medical Association, Detroit, June, 1916

Now in 30,000 mouths we find about 60,000 cavities, and I intend to show what one cavity means to the average laboring man First, there is the slight opening of the interdental space, food packs into the space, irritating the gum Quite naturally he gives up mastication on that side of the mouth, caries progresses until the pulp is exposed, the tooth aches, and he goes home from work, often purchasing a bottle of whisky on the way I have had cases in which the patients have admitted spending their last cent for whisky and had to borrow money to go to the dentist

The pulp in the tooth may die in twenty-four hours, or it may stop aching, only to start again in a few days If the pulp dies, in a period of time we have the acute alveolar abscess and at last in desperation he goes to the dentist and has the tooth extracted During this period of time, due to disuse, quantities of filth have collected over the other teeth on that side of the mouth, caries has started in the tooth next to the one extracted, and within a few months he again goes through with the same experience By this time the other teeth have become decalcified, and within a comparatively short time he loses every tooth on that side of the mouth, and it is easy to understand this man could not be marked 100 per cent in efficiency during this period If we admit the teeth to be necessary to mastication and digestion, we know that the employee cannot enjoy the good health he would have had, had we been able to prevent that first cavity or at least to persuade him to have dental service before it was too late

In 30,000 mouths we find about 18,000 extractions necessary, and experience shows these teeth to be practically all abscessed This is a difficult problem in efficiency, especially so if the findings of the research commission of the National Dental Association in regard to the relation of infections of the mouth to general systemic disorders prove only part truth, but the indications are at the present time that these apparently unimportant foci of infection are the cause of many disorders

The average dentist knows little at the present time regarding the effect of these foci of infection If it is arthritis, stomach ulcer, heart lesions, pernicious anemia or any of the nervous diseases of a neuralgic type, the medical man is consulted If it is true that these foci of infection are causing these obscure diseases, it is time for the dentist to learn more of medicine, so that he may hold intelligent consultation with the physician, and the physician should seek the consultation of intelligent dentists One case along this line I wish to report After working for the company for six years this man laid off in November, 1913, to have a mastoid operation In July, 1915, he applied for reemployment Physical examination showed ankylosis of the knee and poor physical condition The mouth examination showed a very bad case of pyorrhea and several abscessed teeth His mouth may not have been the cause of his trouble, but the surgeon overlooked the possible cause, and the patient should have been sent to a dentist Had this been done, he might at this time be an efficient workman On the other hand, there are no doubt a good many of your patients whom you are burying on account of poor dentistry

I wish to report a case which to my mind shows how bacteria are carried by the blood stream A man injures a tooth in such a way as to kill the pulp After a period of time an alveolar abscess develops I have seen a number of these cases without a cavity in the tooth, no pyorrhea, and gums in a healthy condition There is only one way that infection could occur The bacteria were carried there by the blood stream from some focus of infection If they are carried to the teeth, it follows naturally that they are carried from these blind alveolar abscesses

If a man presents himself to our physical examiners with a suppurating toe-nail or infected finger nail, he is promptly rejected as being unfit for employment, likewise if he has an acute alveolar abscess with a swollen jaw he is rejected until the cause has been removed and the swelling subsides, but we cannot reject these men with 18,000 necessary extractions, knowing or at least suspecting the effect on their efficiency, if we did, it would mean the rejection of 25 per cent of all people applying for employment The best we can do is to advise the removal of these teeth In 30,000 mouths we find 40,000 teeth extracted, and that tells its own story, the inability to properly masticate the food, and you medical men know better than I the results of improper digestion which are bound to follow

One way we can estimate the loss of efficiency due directly to toothache is by watching the piece-worker Very often a man engaged in piece-work will say "Doctor, this tooth has ached for a week" The loss of money to these men runs from $3 to $7 for the week Men suffering for a day report losses of from 35 cents to $1 50

In 30,000 mouths we find 60,000 cavities and 18,000 extractions necessary, 78,000 in all If each one causes an average loss, through waste of time and cost of repair, of $2, it means a cost of $156,000 In New York City last year 67,000 children failed to be promoted to higher grades because of absence, 80 per cent of which can be laid to defective teeth, and it costs New York $1,037,696 to duplicate a year's schooling to these absentees These same children in a few years will be employed by our industrial concerns and a large percentage will fail of promotion on account of poor health due to bad mouth conditions

What can be done by way of prevention? The first thing necessary is the cooperation of the medical man, he is the first to see the pregnant woman, he should instruct her regarding what to eat to supply the necessary mineral salts to build bone and teeth, and send her to the dentist for instruction regarding the care of her mouth The dentist should instruct her regarding the mouth of her child when it arrives, also regarding the care of that mouth after the teeth begin to erupt It is possible to take a child at this time and prevent the formation of cavities, and it is most important that this should be done

We find at the present time a great many dental clinics in the public schools This is a good work, but the child is 6 years of age when he starts school and a great deal of damage has already occurred, so the work of the clinics is largely reparative, but still it is not too late to teach the children oral hygiene They should be taught how to live, which is vastly more important than certain subjects which have been a part of the school curriculum in past years If this were done, they would leave school and enter our industrial institutions better equipped to earn a livelihood

During the past two years dental clinics have been established in a number of large manufacturing concerns These clinics are operated along different lines, but all with the same general idea in view, that of cooperating with the medical departments in bringing about more satisfactory health conditions

---

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS MOCK, CLARK, LEMON AND SMITH

Dr Joseph C Bloodgood, Baltimore I am interested in this question from an academic standpoint, from the standpoint of the teacher We must apply our knowledge of first aid in the introduction to the industrial worker of the larger problem of prevention and the care of his health and efficiency The industrial worker will see quickly a diminution in the long period of disability and a diminution in the number of cases of loss of function from bad results, not of bad surgery, but of the late application of good surgery It is important for the industrial surgeons to know the established rules of surgery today If they wish to influence the laborer their results must be such that there will be no question in the minds of the ones who are helped that it is for their good Along with that, in industrial surgery as in preventive medicine, there must be something else, otherwise our interest will lag, and our efficiency will decrease, and that something else is a research for the solving of the unsettled problems Not one single bit of progress has been made in the treatment of infected wounds for a quarter of a century Surgery of infected wounds was developed twenty-five years ago, but as soon as surgical bacteriology developed clean surgery, we lost interest in it For sixteen years there has been no research on the treatment of infections The development in medical bacteriology led to the protection against typhoid fever Why? Because there was an immediate need for protection We have not any typhus now, but there are some infections that might creep into this country in the future and those are the ones that you should study so that we will be prepared

Dr J W Schereschewsky, Washington, D C I would like to emphasize the wonderful educational effect which is bound to result from the personal relation of the industrial physician to the worker Everybody is agreed that community sanitation, as represented by state and municipal boards of health, has proceeded almost as far as it can go, and the reason for this is that we cannot influence the people, individually, by community sanitation The great importance of personal hygiene in enabling the individual to reach the maximum of his efficiency is being demonstrated from day to day by the data which are being collected It is evident, therefore, if we want to make substantial advances toward our ideals, we must be able to impress on the individual the vital necessity for the care of the body, besides securing the maintenance of a sanitary environment around him all the time, not only in the shop, but in the home

The development of industrial medicine and surgery offers advantages to educate the individual in these particulars which cannot be excelled in any other field The workers, surrounded in the workshop by ideal sanitary conditions, are able to contrast those conditions with the conditions which obtain in their homes In this way they are unconsciously led to desire a higher standard of environment The personal relation of the physician to the worker in the workshop is a means by which the principles of personal hygiene may be so inculcated that they are applied and not regarded as fads of the medical profession, for every day around the worker there will be shining examples of the results of the application of principles of personal hygiene In this way we see that when this science of industrial medicine and surgery is properly developed, we will have at our command a means of popular education which can hardly be excelled There are about 30,000,000 industrial workers in the United States, very nearly one third of the population Probably 90 per cent of the population should be influenced by these means of personal education I think the industrial physician and surgeon has it in his power to influence, more than any other body of men in this country, the consistent development and progress in this country toward ideals of sanitation

Dr W H Price, Detroit If I heard right, Dr Clark tells us that the examinations he has made take, on an average, ten minutes I disagree with Dr Clark From an experience of 15,000 medical examinations, I know that it takes much longer, and I am afraid we do not make as careful an examination as Dr Clark has made I know that last year Dr Fiske reported they took an average of twenty minutes A number of physicians disputed that such a thing as a thorough medical examination in twenty minutes was possible A blood pressure examination will take a minimum of five minutes, and then sometimes it is not accurate and we have to take it two or three times I know that Dr Schereschewsky and his assistant spent forty minutes or forty-five minutes on an average in 30,000 examinations they made in cooperation with our board, so that I believe that ten minutes is rather a short time This brings me again to the question of the absolute unworthiness of statistics based on a nonstandardized examination If one examines in five minutes, another in ten, another in forty-five, etc, and all those figures come together, how can we compare the results? I believe that nothing better can be done by this section than to appoint a Committee on Standardization of Industrial Medical Examinations, so that in the future we should be able to compare those examinations

Dr Frederick L Van Sickle, Olyphant, Pa I feel that we have not ventilated the subject to the people on whom we must depend to carry out the very admirable suggestions that have been made by Dr Mock and Dr Clark I practice in the anthracite coal fields of Pennsylvania, where we have a combination of traumatism and the introduction of foreign bodies Wounds are made at quite a distance from the emergency hospital, so that the ideal measures that have been suggested by Dr Mock and Dr Clark are not possible My point particularly is efficiency insurance in medical and surgical work as applied to social and the new laws that are coming into existence in the United States Thirty three states have workmen's compensation laws, and in five states health insurance measures will be introduced shortly Some of the ideas introduced by Dr Mock are Utopian, but it is necessary as a step in the progress of this work to have some educational propaganda made by which the men who are most vitally interested, that is, the local practitioner who receives the appointment for this kind of work, be brought up to some particular standard of efficiency The medical examination is also made in a very superficial manner It is evident that we must have some method of standardization of examinations of the workman I feel grateful that the questions of social insurance have been taken up by the American Medical Association and it has seen fit to confirm the report of the Reference Committee on Legislation and Political Action which places the committee of the Judicial Council of the Association (which was appointed last year on social health and insurance), in a way to act, and it has been recommended to the various states that they appoint a like committee from whom this information can be obtained

Dr D B Lowe, Akron, Ohio Dr Clark made a plea for a complete examination A complete examination to me means a stripped examination In the organization which I represent, there were 12,000 examinations made on employees at the time physical examinations were instituted These 12,000 examinations were made by part-time physicians who spent practically only two hours a day at the shop In the 12,000 there is not one case of tuberculosis reported The urinalysis may or may not be necessary in certain cases Blood pressure may prove otherwise on general findings I have come to the conclusion that it is best for all our examiners to make a complete examination, examine the urine and take blood pressures, and sometimes even examine blood All of us lack sufficient training, however, if we do some laboratory work along with the physical examinations, it will tend to train us I do not cast any reflections on the men we have in our employ because they must be graduates of a Class A school and have at least a year's training in a recognized hospital with six months' service on the medical side Running through 150 men a day, an average of about thirty-six to the examiner, with a large organization calling for men that must be put to work, it is impossible at the present time to select men for the work It may be possible in a smaller organization, but we cannot do it As to the rejection for hernia, the laws of various states differ In Ohio we do not have to reject every hernia case, if the company will stand behind us on the question of finance We made arbitrarily three classes those who have a small hernia, those who have a larger hernia, and those who have a complete hernia, if I may put it in that way, the first class without a truss, the second class with a truss, and the third class we reject In two months we took 125 men Seventy-five per cent of those who applied with hernia we put into the shop on any kind of work Some are doing very heavy work Of those eighty-six remained with us at the end of two months when this material was taken We have had one whose hernia came down, that required a $5 truss It costs our company $35 a man to train their men If they are in our employ at the end of six months we will not operate on them ourselves free of charge, but we will operate on them and the fee will be made according to the family conditions, as to whether the man is in debt, as to whether he is paying for his home, etc Maybe the company will, if necessary, underwrite those cases and pay the surgeon and the hospital bill, and the money will be deducted from the man's salary at about 10 per cent of his pay on each pay day It makes, probably, an average of about $5 a month, and it takes a man in the neighborhood of fourteen months to pay the whole bill In the intermediate cases out of the twenty-five we have operated on under this plan it has cost the company, due to those who have left the company and refused to pay, and various other reasons, $14 a man It cost $35 to put them in, $14 to keep them, so we consider it is quite a good investment As to the time required in making a physical examination, since the first of November on stripped examinations made by full time physicians we have examined 12 000 men Our turn-over is quite large Of the 12,000 who passed into the shop, four have developed tuberculosis since that time

Dr C G Farnum, Peoria, Ill Some one said that Dr Mock's paper approaches the Utopian Possibly, it does, but it is absolutely practical There is not one single thing that Dr Mock suggested that cannot be done, and be done easily One of the reasons it is easy is because he stands so strongly for personal contact with the men You cannot be doctors alone in this work, you must be sociologists and you will be accused occasionally of being Socialists There is not one thing that is more valuable in the work that Dr Mock has done than his personal contact with the men When these men come to know that they have the privilege and the opportunity to come in and talk with you they will do so not about their hernia, not about their scratched fingers, but with regard to their habits of eating and drinking and sleeping and housing and sanitation and all of those things that come into the daily routine of a man's life I want to speak particularly of physical examination I do not care how many legs or hands a man has, if I can put him where I want him in the shop And, if there is any man who is falling short in the work of placing his men he has taken but a part of one small step in this work because that is the most valuable thing to the company, and it is the biggest thing to the man People are writing me constantly 'What is your standard of rejections' and I tell them, 'We are not running an athletic club nor turnverein, we are running a manufacturing institution If a man has but one leg, I put him in a one-legged man s job And if a man has one arm I do the same thing When it comes to the matter of eyes, the problem is bigger It does not matter about the condition of a man if you tell him what is wrong and get him headed right and put him at work that he can do and do safely That is what he wants, and that is what he is there *for*, and that is our obligation to him and to the company There is another thing that has not been brought out in the discussions and that is the matter of age, and physical condition and their relation to responsibility and reliability Where is our labor turn over coming from? We have worked out some statistics that show that our physically perfect men and there were not very many of them, were the worst aggregation we have, from the standpoint of labor turn-over This matter of fitting men to jobs is wonderfully important and the matter of coming intimately in contact with the men is also important Your *position* in your de[illegible] must be absolute, if it is not, then your work is not going to carry The department of employment, the department of safety and the medical or sanitary departments are so intricately interwoven, that if you try to separate them, you are going to curtail the most valuable portion of the work of each one of them

Dr Charles J Hastings, Toronto, Ont It seems to me that we have been "found asleep at the switch" We have been doing many things that we ought not to have done, and we have left undone many things which we ought to have done, and we are just waking up to it now I was glad to hear the former speaker refer to the social problems in public health administration We realize, however, that no organization of public health administration is at all complete without a division of social service and without a division of industrial hygiene Public health administration at the present time stands for race betterment, for the developing of a fitter race The control of communicable diseases only constitutes a fractional part of public health administration

Dr Eugene L Fisk, New York The time consumed by the Life Extension Institute in making physical examinations has been mentioned It should be explained that the history taking is done in advance of that examination History blanks are filled out by the employee in advance of examination, so that a lot of time is saved Then the examiner concentrates on the physical examination, and he takes from twenty minutes to half an hour, depending on his training It is important that we should standardize this work A very valuable examination can be made in ten minutes, even in five minutes No reflection whatever should be cast on the great value of the work done by Dr Clark His examination was a most valuable one, it brought out most interesting things, but I think that perhaps in the same space of time, other things could be added and a complete physical examination made For example, the lymphatics are mentioned, the heart, and various organs of the body, but no mention is made of the arterial system or the examination of the radicals and brachials An examination of these structures and even the eyegrounds, with modern instruments could be made very quickly, and surely there is no more important part of a man's body than his arteries There is one fact which is brought out in our service, and that is the unreliability of blood pressure as a guide to the condition of the arterial system There is a common impression that if a man's blood pressure is normal, his arteries are normal The majority of individuals with definitely thickened arteries have either normal blood pressure or low blood pressure I cannot speak too strongly of the possibility of this work in a sociologic way, of the opportunities to teach these men how to live Like Dr Farnum, I have been out among these people and I have put my ear down to their naked sweaty chests I have tried to carry to them this philosophy of right living They respond and they respond more readily and more intelligently than even men in the higher walks of life who are supposed to have more intelligence They are not so cynical or so skeptical and you can explain to them the fundamental principle that the human machine needs inspection and care just the same as the inanimate machines that are under their charge

Dr C A Lauffer Wilkinsburg, Pa For eight years I have been associated with this work in the capacity of medical director The Westinghouse Electric and Manufacturing Company has a works dispensary known as the Relief Department, in the East Pittsburgh plant We are taking care of about 450 patients a day We treat an average of 110 new traumatic cases each day I have been extremely interested in these papers because their solutions correspond very closely with the way we have met these same conditions About one third of our traumatic cases are eye cases, another third fingers, the balance are miscellaneous It might be well to define under five heads the different types of work which come to the surgeon in individual practice

First of all is the examination of new employees We have recently entered this field We prepared a list of fourteen different classes of conditions in which we think we should reject prospective employees However, we have taken care of all men, who have been in the employ of the company previous to the inauguration of the physical examinations

MEDICAL LIBRARY 2960

cerns These clinics are operated along different lines, but all with the same general idea in view, that of cooperating with the medical departments in bringing about more satisfactory health conditions

---

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS MOCK, CLARK, LEMON AND SMITH

Dr Joseph C Bloodgood, Baltimore I am interested in this question from an academic standpoint, from the standpoint of the teacher We must apply our knowledge of first aid in the introduction to the industrial worker of the larger problem of prevention and the care of his health and efficiency The industrial worker will see quickly a diminution in the long period of disability and a diminution in the number of cases of loss of function from bad results, not of bad surgery, but of the late application of good surgery It is important for the industrial surgeons to know the established rules of surgery today If they wish to influence the laborer their results must be such that there will be no question in the minds of the ones who are helped that it is for their good Along with that, in industrial surgery as in preventive medicine, there must be something else, otherwise our interest will lag, and our efficiency will decrease, and that something else is a research for the solving of the unsettled problems Not one single bit of progress has been made in the treatment of infected wounds for a quarter of a century Surgery of infected wounds was developed twenty-five years ago, but as soon as surgical bacteriology developed clean surgery, we lost interest in it For sixteen years there has been no research on the treatment of infections The development in medical bacteriology led to the protection against typhoid fever Why? Because there was an immediate need for protection We have not any typhus now, but there are some infections that might creep into this country in the future, and those are the ones that you should study so that we will be prepared

Dr J W Schereschewsky, Washington, D C I would like to emphasize the wonderful educational effect which is bound to result from the personal relation of the industrial physician to the worker Everybody is agreed that community sanitation, as represented by state and municipal boards of health, has proceeded almost as far as it can go, and the reason for this is that we cannot influence the people individually, by community sanitation The great importance of personal hygiene in enabling the individual to reach the maximum of his efficiency is being demonstrated from day to day by the data which are being collected It is evident, therefore if we want to make substantial advances toward our ideals, we must be able to impress on the individual the vital necessity for the care of the body, besides securing the maintenance of a sanitary environment around him all the time, not only in the shop, but in the home

The development of industrial medicine and surgery offers advantages to educate the individual in these particulars which cannot be excelled in any other field The workers, surrounded in the workshop by ideal sanitary conditions, are able to contrast those conditions with the conditions which obtain in their homes In this way they are unconsciously led to desire a higher standard of environment The personal relation of the physician to the worker in the workshop is a means by which the principles of personal hygiene may be so inculcated that they are applied and not regarded as fads of the medical profession, for every day around the worker there will be shining examples of the results of the application of principles of personal hygiene In this way we see that when this science of industrial medicine and surgery is properly developed, we will have at our command a means of popular education which can hardly be excelled There are about 30,000,000 industrial workers in the United States, very nearly one third of the population Probably 90 per cent of the population should be influenced by these means of personal education I think the industrial physician and surgeon has it in his power to influence, more than any other body of men in this country, the consistent development and progress in this country toward ideals of sanitation

Dr W H Price, Detroit If I heard right, Dr Clark tells us that the examinations he has made take, on an average, ten minutes I disagree with Dr Clark From an experience of 15,000 medical examinations, I know that it takes much longer, and I am afraid we do not make as careful an examination as Dr Clark has made I know that last year Dr Fiske reported they took an average of twenty minutes A number of physicians disputed that such a thing as a thorough medical examination in twenty minutes was possible A blood pressure examination will take a minimum of five minutes, and then sometimes it is not accurate and we have to take it two or three times I know that Dr Schereschewsky and his assistant spent forty minutes or forty-five minutes on an average in 30,000 examinations they made in cooperation with our board, so that I believe that ten minutes is rather a short time This brings me again to the question of the absolute unworthiness of statistics based on a nonstandardized examination If one examines in five minutes, another in ten, another in forty-five, etc, and all those figures come together, how can we compare the results? I believe that nothing better can be done by this section than to appoint a Committee on Standardization of Industrial Medical Examinations, so that in the future we should be able to compare those examinations

Dr Fredrick L Van Sickle, Olyphant, Pa I feel that we have not ventilated the subject to the people on whom we must depend to carry out the very admirable suggestions that have been made by Dr Mock and Dr Clark I practice in the anthracite coal fields of Pennsylvania, where we have a combination of traumatism and the introduction of foreign bodies Wounds are made at quite a distance from the emergency hospital, so that the ideal measures that have been suggested by Dr Mock and Dr Clark are not possible My point particularly is efficiency insurance in medical and surgical work as applied to social and the new laws that are coming into existence in the United States Thirty-three states have workmen's compensation laws, and in five states health insurance measures will be introduced shortly Some of the ideas introduced by Dr Mock are Utopian, but it is necessary as a step in the progress of this work to have some educational propaganda made by which the men who are most vitally interested, that is, the local practitioner who receives the appointment for this kind of work, be brought up to some particular standard of efficiency The medical examination is also made in a very superficial manner It is evident that we must have some method of standardization of examinations of the workman I feel grateful that the questions of social insurance have been taken up by the American Medical Association and it has seen fit to confirm the report of the Reference Committee on Legislation and Political Action which places the committee of the Judicial Council of the Association (which was appointed last year on social health and insurance), in a way to act, and it has been recommended to the various states that they appoint a like committee from whom this information can be obtained

Dr D B Lowe, Akron, Ohio Dr Clark made a plea for a complete examination A complete examination to me means a stripped examination In the organization which I represent, there were 12,000 examinations made on employees at the time physical examinations were instituted These 12,000 examinations were made by part-time physicians who spent practically only two hours a day at the shop In the 12,000 there is not one case of tuberculosis reported The urinalysis may or may not be necessary in certain cases Blood pressure may prove otherwise on general findings I have come to the conclusion that it is best for all our examiners to make a complete examination, examine the urine and take blood pressures, and sometimes even examine blood All of us lack sufficient training, however, if we do some laboratory work along with the physical examinations, it will tend to train us I do not cast any reflections on the men we have in our employ because they must be graduates of a Class A school and have at least a year's training in a recognized hospital with six months' service on the medical side Running through 150 men a day, an average of about thirty-six to the examiner, with a large organization calling for men that must be put to work, it is impossible at the present time to select men for the work It may be possible in a smaller organization, but we cannot do it As to the rejection for hernia, the laws of various states differ In Ohio we do not have to reject every hernia case, if the company will stand behind us on the question of finance We made arbitrarily three classes those who have a small hernia, those who have a larger hernia, and those who have a complete hernia, if I may put it in that way, the first class without a truss, the second class with a truss and the third class we reject In two months we took 125 men Seventy-five per cent of those who applied with hernia we put into the shop, on any kind of work Some are doing very heavy work Of those eighty-six remained with us at the end of two months when this material was taken We have had one whose hernia came down, that required a $5 truss It costs our company $35 a man to train their men If they are in our employ at the end of six months we will not operate on them ourselves free of charge, but we will operate on them and the fee will be made according to the family conditions, as to whether the man is in debt, as to whether he is paying for his home, etc Maybe the company will, if necessary, underwrite those cases and pay the surgeon and the hospital bill, and the money will be deducted from the man's salary at about 10 per cent of his pay on each pay day It makes, probably, an average of about $5 a month, and it takes a man in the neighborhood of fourteen months to pay the whole bill In the intermediate cases, out of the twenty-five we have operated on under this plan it has cost the company, due to those who have left the company and refused to pay, and various other reasons, $14 a man It cost $35 to put them in, $14 to keep them, so we consider it is quite a good investment As to the time required in making a physical examination, since the first of November on stripped examinations made by full time physicians we have examined 12,000 men Our turn-over is quite large Of the 12,000 who passed into the shop, four have developed tuberculosis since that time

DR C G FARNUM, Peoria, Ill Some one said that Dr Mock's paper approaches the Utopian Possibly, it does, but it is absolutely practical There is not one single thing that Dr Mock suggested that cannot be done, and be done easily One of the reasons it is easy is because he stands so strongly for personal contact with the men You cannot be doctors alone in this work, you must be sociologists and you will be accused occasionally of being Socialists There is not one thing that is more valuable in the work that Dr Mock has done than his personal contact with the men When these men come to know that they have the privilege and the opportunity to come in and talk with you they will do so not about their hernia, not about their scratched fingers, but with regard to their habits of eating and drinking and sleeping and housing and sanitation and all of those things that come into the daily routine of a man's life. I want to speak particularly of physical examination I do not care how many legs or hands a man has, if I can put him where I want him in the shop And, if there is any man who is falling short in the work of placing his men, he has taken but a part of one small step in this work because that is the most valuable thing to the company, and it is the biggest thing to the man People are writing me constantly "What is your standard of rejections," and I tell them "We are not running an athletic club nor turnverein, we are running a manufacturing institution " If a man has but one leg, I put him in a one-legged man's job And if a man has one arm, I do the same thing When it comes to the matter of eyes the problem is bigger It does not matter about the condition of a man if you tell him what is wrong and get him headed right and put him at work that he can do and do safely That is what he wants and that is what he is there for and that is our obligation to him and to the company There is another thing that has not been brought out in the discussions and that is the matter of age, and physical condition and their relation to responsibility and reliability Where is our labor turn-over coming from? We have worked out some statistics that show that our physically perfect men and there were not very many of them, were the worst aggregation we have, from the standpoint of labor turn-over This matter of fitting men to jobs is wonderfully important and the matter of coming intimately in contact with the men is also important. Your position in your department [illegible] must be absolute, if it is not, then your work is not going to carry The department of employment, the department of safety and the medical or sanitary departments are so intricately interwoven, that if you try to separate them, you are going to curtail the most valuable portion of the work of each one of them

DR CHARLES J HASTINGS, Toronto, Ont It seems to me that we have been "found asleep at the switch" We have been doing many things that we ought not to have done, and we have left undone many things which we ought to have done, and we are just waking up to it now I was glad to hear the former speaker refer to the social problems in public health administration We realize, however, that no organization of public health administration is at all complete without a division of social service and without a division of industrial hygiene Public health administration at the present time stands for race betterment, for the developing of a fitter race The control of communicable diseases only constitutes a fractional part of public health administration

DR EUGENE L FISK, New York The time consumed by the Life Extension Institute in making physical examinations has been mentioned It should be explained that the history taking is done in advance of that examination History blanks are filled out by the employee in advance of examination, so that a lot of time is saved Then the examiner concentrates on the physical examination, and he takes from twenty minutes to half an hour, depending on his training It is important that we should standardize this work A very valuable examination can be made in ten minutes, even in five minutes No reflection whatever should be cast on the great value of the work done by Dr Clark His examination was a most valuable one, it brought out most interesting things, but I think that perhaps in the same space of time other things could be added and a complete physical examination made For example, the lymphatics are mentioned, the heart, and various organs of the body, but no mention is made of the arterial system or the examination of the radicals and brachials An examination of these structures, and even the eye-grounds, with modern instruments could be made very quickly, and surely there is no more important part of a man's body than his arteries There is one fact which is brought out in our service, and that is the unreliability of blood pressure as a guide to the condition of the arterial system There is a common impression that if a man's blood pressure is normal, his arteries are normal The majority of individuals with definitely thickened arteries have either normal blood pressure or low blood pressure I cannot speak too strongly of the possibility of this work in a sociologic way, of the opportunities to teach these men how to live Like Dr Farnum I have been out among these people and I have put my ear down to their naked sweaty chests I have tried to carry to them this philosophy of right living They respond, and they respond more readily and more intelligently than even men in the higher walks of life who are supposed to have more intelligence They are not so cynical or so skeptical and you can explain to them the fundamental principle that the human machine needs inspection and care just the same as the inanimate machines that are under their charge

DR C A LAUFFER Wilkinsburg, Pa For eight years I have been associated with this work in the capacity of medical director The Westinghouse Electric and Manufacturing Company has a works dispensary known as the Relief Department, in the East Pittsburgh plant We are taking care of about 450 patients a day We treat an average of 110 new traumatic cases each day I have been extremely interested in these papers because their solutions correspond very closely with the way we have met these same conditions About one third of our traumatic cases are eye cases, another third fingers, the balance are miscellaneous It might be well to define under five heads the different types of work which come to the surgeon in individual practice

First of all is the examination of new employees We have recently entered this field We prepared a list of fourteen different classes of conditions in which we think we should reject prospective employees However, we have taken care of all men, who have been in the employ of the company previous to the inauguration of the physical examinations

Dr. Robert [illegible] Library
[illegible] Medical College
MEDICAL LIBRARY
2-960

The second type of work is surgical cases, chiefly accidents occurring within the plant We get patients immediately after the accident We think it is a misfortune to have first aid work preceding the work of the physician We have surgeons on duty twenty-four hours each day, and we instruct injured men to come to us immediately The work of the first aid man is generally mischievous, we want to have the patient immediately, while his wound is still bleeding The third type of work we have to do relates to sickness All employees who are not feeling well are encouraged to come to us We give them emergency medical treatment We send home those employees whose temperature is elevated, also those whose temperature is subnormal The fourth service of our department is a "diagnostic clearing house" Many of these men, who may be sent to hospitals for herniotomies, or various other operative conditions, are given advice as to the proper procedure They are referred to specialists in various lines of work The fifth line of our work is with relation to our relief fund Employees of our company may pay a certain proportion of their wages to secure disability benefits for periods of disability arising from accidents occurring at home and in consequence of sickness We are paying about $15,000 a month out of the relief fund, and it requires much labor to review the diagnoses that are presented to us, and to pass on the statements that are brought to us by the employees, and the certificates which are presented from their attending physicians Proof of claims for compensation insurance for periods of disability resulting from accidents occurring within the plant must also be adjusted These are paid out of the company's compensation fund The field of the surgeon in industrial practice is a wide one We have entirely too little available time for the stupendous work at our disposal

Dr W H Lipman, Chicago Regarding the time for the examination, I believe it would be well to establish a standard for general work, that is, have a standard that can be applied generally, as to what to look for But I do not believe it is possible to say how much time we should take and how much time we should not take to examine a man We might want to take forty-five minutes to examine one man and two minutes and a half to examine another When a man or woman comes in looking anemic, or with a flushed face, one would naturally make a longer examination I have been doing this work in Chicago for one of the large packing houses for eleven years, at the beginning very superficially, and I am free to admit very inefficiently, but we have gradually developed and finally, after studying the methods which have been in use all over the country and their results, we reject men for just one cause, and nothing else, and that is contagious diseases When a man presents a case of a contagious disease of short duration, we ask him to call again in a reasonable time, and if he has been cured, or is well, we will accept him, but outside of that we will reject for absolutely nothing We find a man with a certain defect, we put him to work Later on we advise him what to do for himself Industrial medicine and surgery is perhaps attracting more attention than anything else Some of the papers and some of the discussions have dwelt on the advisability of telling the employer what a fine investment this medical work among their employees is Some have gone so far as to figure out in dollars and cents just how much money they are going to save by saving the lives of their employees, by reducing pain, by prolonging life and so on I believe that is a great mistake In the first place, it is wrong, because nobody can tell us how much a human life is worth, or how much pain and suffering cost And, second, I believe that the average employer is — if I may use that expression — a mixed culture It is true he has a very great affinity for the dollar, but I believe that he is a man after all, and I think when he comes to the final issue he is more easily approached when you appeal to his humanity, rather than to his love for the dollar Furthermore, if you insist on showing him just how much money he is going to make, the time will come when you will not be able to do that, and then if you depend on your work to convince him that he is going to make money, you will lose out in the end

Dr Harry E Mock, Chicago As to the length of time these physical examinations should take, ten minutes is entirely too short a time for the ordinary physical examination where the history, temperature, pulse, blood pressure, height and weight, eye test, etc, must be taken by the examining physician But the men actually doing this work are engaged by great industries who demand that their employees be returned to work in as short a time as possible, therefore, it is necessary for the company surgeon to work out very efficient systems, in order to make this examination as rapidly as possible We have nurses who do the preliminary work of eye test, ear test, pulse, temperature, weight, etc, and then the employee enters a dressing room, strips, and comes before a doctor for his examination This routine examination can be done in from ten to twelve minutes If a man is found with a very badly diseased condition, he is sent to the chief of staff for further study, and it may take an hour to complete this examination But any one engaging in this work will find ten or twelve minutes sufficient time for the routine examinations The second point is that these examinations are not made for the purpose of throwing out those too old to work, those with slightly diseased conditions, and those with chronic diseases that interfere with only certain types of work, namely heavy work They are made for the protection of the old working force against contagious diseases and for the protection of the applicant himself if he has a disease that makes work of any kind detrimental to him Every industry should assume its share of responsibility toward society until the state takes up that burden We have no right to reject old men, or any one else except those mentioned There are just two things to reject on, contagious disease that affects your working force and a very bad heart, or blindness, or some condition that makes it impossible for that man to work for his own good

Dr W Irving Clark, Jr, Worcester, Mass The preciseness of my paper was to answer a great many questions which I have had written to me in the last two or three years on our work, and is simply an answer with regard to what we are doing, and how we are trying to do it We place all our men just as carefully as we can We would rather have a deaf and dumb man than anybody else They mind their business, and they never make any trouble We take all the one-armed men They are the finest fellows for work if they can do it, that I know of If we can find a job for a one-legged man, we will take him I think it was Dr Farnum who brought out the question of cooperation, the safety engineering department, the medical department, and the employment department should actively cooperate, they should be in one building and should form a separate department, with these three subdivisions Dr Fiske spoke about the completeness of examination and the time required I would rather take forty-five minutes to make an examination than ten But, what are you going to do when there are 100 men lined up, and the employment clerk says 'We will have to get these men through," and there are more behind them We must realize that our business is to get men into the factory and to keep them working if we are factory physicians We would like to be sociologists, but unfortunately, we have to work in a factory, and there are certain things in a factory that have to be recognized Time is one of the most important elements in factory work

Effect of the "Movies" on Eye Muscles—When looking at a motion picture the pupil is contracted to a somewhat smaller opening than when viewing a still picture having the same illumination, and when the flicker in the motion picture is pronounced, the pupil of the eye can be seen to tremble slightly as if attempting to follow each fluctuation of light This may lead to overstimulation and permanent injury One investigator, in writing on this particular phase, concludes by stating that this constant contraction and dilation must gradually strengthen the muscles of the eye and so eventually develop them to the point were strain would not be caused From this opinion, however, leading ophthalmologists differ, and believe that the fatigue caused by overstimulation due to flicker frequently passes beyond physiologic limits and must eventually produce deterioration —Gordon L Berry, *Public Health*, November, 1916

THE SANITATION OF PUBLIC MARKETS *

DONALD B ARMSTRONG, M D, M A, M S
Assistant Secretary, National Association for the Study and Prevention of Tuberculosis Executive Officer, Community Tuberculosis Experiment
NEW YORK

Out of an income of less than $1,000 a year, the average urban family of five in most large American cities has to spend from 40 to 50 per cent of their income for food Undoubtedly an important factor contributing to this large percentage is the cost of municipal food handling and distributing, as was indicated by a recent study in New York City, where it was ascertained that about 37 cents out of every consumer's dollar went for the cost of municipal food transportation Public markets are considered by many an essential factor in combating the high cost of foods resulting from the present individualistic methods of municipal food handling The past few years have seen many experiments along market lines, either under public, semipublic or private control, either temporary or permanent in character It would seem that the most effective results might be expected with the highest degree of municipal control, including a regulation of rents, or retail food prices and consequently of profits Obviously, if a public market is properly situated, it can effect still further economies to the consumer by the elimination of the cost of delivery and the loss resulting from the operation of the stores on a credit basis

The establishment of public markets, especially when of a temporary and experimental character, introduces into the community life many problems of intimate sanitary and hygienic importance, problems which the public market has in common with the retail store to a large extent Concentration, however, of retail business in certain areas, possibly under one roof, increases the magnitude of the problem and at the same time enhances the directness and simplicity with which a sanitary control can be established In any event, whether under private or public auspices, any municipality must meet the responsibility of establishing and maintaining adequate sanitary and hygienic regulations in connection with the city's food distributing system

Sanitary food control is of interest from several points of view In the first place, there are the representatives of the municipality, usually the health department officials, who have the responsibility of inspection and law enforcement Of great significance in this connection are the recent findings of health departments, perhaps especially the New York City department of health, to the effect that intelligent, educational inspection is tremendously more efficient, from the point of view of accomplishing results, than is any amount of uninstructive visiting, legal prosecutions and insignificant fines

Further, the dealer himself is intimately concerned in sanitary law compliance It is essential that he should be made to realize the economic importance of sanitary food protection and waste prevention, in addition to the health hazards of careless food infection

Finally, there is the consumer, the purchaser, who is interested in food protection and desires food protection, aroused to the necessity by motives of disease prevention, cleanliness, decency, and estheticism

From whatever point of view the problem is approached, however, those interested soon realize that the special problems of market sanitation are, in the main, three in number In the first place, because of the perishability of ordinary food products, and because of the risks of disease transmission, there are dangers of contamination and possible infection, by means of dust, dirt, flies and dirty fingers It is certainly conceivable that tuberculosis, typhoid fever and other diseases may be, and perhaps frequently are, transmitted in this way Further, there are the special dangers of decomposition, the rare development of genuine ptomains, the more frequent pathologic bacterial infections, etc Finally, there must be mentioned the comparatively insignificant hazards resulting from adulterated or preserved foods, a problem in fraud prevention largely of economic, rather than of sanitary, significance Such a classification does not, of course, include certain other possibilities, such as the presence of natural poisons, as in mushrooms, the presence of animal parasites, as in pork, the development of a specific poison, such as solanin in potato sprouts, and special individual idiosyncrasies, as pathologic reaction to egg protein It ignores entirely what would seem to be the most important food factor in health conservation, namely, proper dietary food selection, a factor of hygienic rather than of sanitary importance and one which is, therefore, not apropos at this point in the discussion

To confine the discussion largely to the sanitary aspects, it might, perhaps, for the sake of clearness, be best to adopt a rough classification of the major points in market sanitary control and to discuss these very briefly under the following headings

PRODUCTS AND THEIR CARE, LABORATORY CONTROL

Chemical Analyses—It is, of course, possible nowadays to find in most large cities adequate facilities for the chemical study of foods offered for sale in municipal markets, and therefore, more or less under municipal guarantee Such analyses should be made to detect illegal adulterants or preservatives and to insure protection against the sale of deteriorated or decomposed products

Bacteriologic Analyses—Routine procedures of this kind are, of course, essential if milk and dairy products are permitted to be handled in the market Bacteriologic analyses to detect contamination of foods from various sources may, from time to time, be worth while Consequently the necessity for municipal equipment to meet demands in this field should be recognized when market plans are being developed

Calorific Analyses—This is the type of analysis and check which cities will have to recognize in the future Eventually governmental authority will have to take the responsibility for food standardization, and if this standardization is to be on a rational basis, calorific values will have to be employed Further, if the purchaser is ever to be educated to the extent that she can buy her food supply on an intelligent food value basis, there will have to be mechanism for routine, calorific food analyses In the present state of development an equipment of this kind cannot, of course, be considerered a prerequisite to a market establishment At the same time, its need should be emphasized, so that in the future it may become an essential part of municipal market control Again, it must be pointed out that this is, of course, of hygienic rather than of sanitary importance

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

The second type of work is surgical cases, chiefly accidents occurring within the plant. We get patients immediately after the accident. We think it is a misfortune to have first aid work preceding the work of the physician. We have surgeons on duty twenty-four hours each day, and we instruct injured men to come to us immediately. The work of the first aid man is generally mischievous, we want to have the patient immediately, while his wound is still bleeding. The third type of work we have to do relates to sickness. All employees who are not feeling well are encouraged to come to us. We give them emergency medical treatment. We send home those employees whose temperature is elevated, also those whose temperature is subnormal. The fourth service of our department is a "diagnostic clearing house." Many of these men, who may be sent to hospitals for herniotomies, or various other operative conditions, are given advice as to the proper procedure. They are referred to specialists in various lines of work. The fifth line of our work is with relation to our relief fund. Employees of our company may pay a certain proportion of their wages to secure disability benefits for periods of disability arising from accidents occurring at home, and in consequence of sickness. We are paying about $15,000 a month out of the relief fund, and it requires much labor to review the diagnoses that are presented to us, and to pass on the statements that are brought to us by the employees, and the certificates which are presented from their attending physicians. Proof of claims for compensation insurance for periods of disability resulting from accidents occurring within the plant must also be adjusted. These are paid out of the company's compensation fund. The field of the surgeon in industrial practice is a wide one. We have entirely too little available time for the stupendous work at our disposal.

DR. W. H. LIPMAN, Chicago: Regarding the time for the examination, I believe it would be well to establish a standard for general work, that is, have a standard that can be applied generally, as to what to look for. But I do not believe it is possible to say how much time we should take and how much time we should not take to examine a man. We might want to take forty-five minutes to examine one man and two minutes and a half to examine another. When a man or woman comes in looking anemic, or with a flushed face, one would naturally make a longer examination. I have been doing this work in Chicago for one of the large packing houses for eleven years, at the beginning very superficially, and I am free to admit very inefficiently, but we have gradually developed and finally, after studying the methods which have been in use all over the country and their results, we reject men for just one cause, and nothing else, and that is contagious diseases. When a man presents a case of a contagious disease of short duration, we ask him to call again in a reasonable time, and if he has been cured, or is well, we will accept him, but outside of that we will reject for absolutely nothing. We find a man with a certain defect, we put him to work. Later on we advise him what to do for himself. Industrial medicine and surgery is perhaps attracting more attention than anything else. Some of the papers and some of the discussions have dwelt on the advisability of telling the employer what a fine investment this medical work among their employees is. Some have gone so far as to figure out in dollars and cents just how much money they are going to save by saving the lives of their employees, by reducing pain, by prolonging life and so on. I believe that is a great mistake. In the first place, it is wrong, because nobody can tell us how much a human life is worth, or how much pain and suffering cost. And, second, I believe that the average employer is — if I may use that expression — a mixed culture. It is true he has a very great affinity for the dollar, but I believe that he is a man after all, and I think when he comes to the final issue he is more easily approached when you appeal to his humanity, rather than to his love for the dollar. Furthermore, if you insist on showing him just how much money he is going to make, the time will come when you will not be able to do that, and then if you depend on your work to convince him that he is going to make money, you will lose out in the end.

DR. HARRY E. MOCK, Chicago: As to the length of time these physical examinations should take, ten minutes is entirely too short a time for the ordinary physical examination where the history, temperature, pulse, blood pressure, height and weight, eye test, etc., must be taken by the examining physician. But the men actually doing this work are engaged by great industries who demand that their employees be returned to work in as short a time as possible, therefore, it is necessary for the company surgeon to work out very efficient systems, in order to make this examination as rapidly as possible. We have nurses who do the preliminary work of eye test, ear test, pulse, temperature, weight, etc., and then the employee enters a dressing room, strips, and comes before a doctor for his examination. This routine examination can be done in from ten to twelve minutes. If a man is found with a very badly diseased condition, he is sent to the chief of staff for further study, and it may take an hour to complete this examination. But any one engaging in this work will find ten or twelve minutes sufficient time for the routine examinations. The second point is that these examinations are not made for the purpose of throwing out those too old to work, those with slightly diseased conditions, and those with chronic diseases that interfere with only certain types of work, namely heavy work. They are made for the protection of the old working force against contagious diseases and for the protection of the applicant himself if he has a disease that makes work of any kind detrimental to him. Every industry should assume its share of responsibility toward society until the state takes up that burden. We have no right to reject old men, or any one else except those mentioned. There are just two things to reject on, contagious disease that affects your working force, and a very bad heart, or blindness, or some condition that makes it impossible for that man to work for his own good.

DR. W. IRVING CLARK, JR., Worcester, Mass.: The preciseness of my paper was to answer a great many questions which I have had written to me in the last two or three years on our work, and is simply an answer with regard to what we are doing, and how we are trying to do it. We place all our men just as carefully as we can. We would rather have a deaf and dumb man than anybody else. They mind their business, and they never make any trouble. We take all the one-armed men. They are the finest fellows for work, if they can do it, that I know of. If we can find a job for a one legged man, we will take him. I think it was Dr. Farnum who brought out the question of cooperation, the safety engineering department, the medical department, and the employment department should actively cooperate, they should be in one building and should form a separate department, with these three subdivisions. Dr. Fiske spoke about the completeness of examination and the time required. I would rather take forty-five minutes to make an examination than ten. But, what are you going to do when there are 100 men lined up, and the employment clerk says 'We will have to get these men through," and there are more behind them. We must realize that our business is to get men into the factory and to keep them working, if we are factory physicians. We would like to be sociologists, but unfortunately, we have to work in a factory, and there are certain things in a factory that have to be recognized. Time is one of the most important elements in factory work.

Effect of the "Movies" on Eye Muscles.—When looking at a motion picture the pupil is contracted to a somewhat smaller opening than when viewing a still picture having the same illumination, and when the flicker in the motion picture is pronounced, the pupil of the eye can be seen to tremble slightly as if attempting to follow each fluctuation of light. This may lead to overstimulation and permanent injury. One investigator, in writing on this particular phase, concludes by stating that this constant contraction and dilation must gradually strengthen the muscles of the eye and so eventually develop them to the point were strain would not be caused. From this opinion, however, leading ophthalmologists differ, and believe that the fatigue caused by overstimulation due to flicker frequently passes beyond physiologic limits and must eventually produce deterioration.—Gordon L. Berry, *Public Health*, November, 1916.

THE SANITATION OF PUBLIC MARKETS*

DONALD B. ARMSTRONG, M.D., M.A., M.S.
Assistant Secretary, National Association for the Study and Prevention of Tuberculosis; Executive Officer, Community Tuberculosis Experiment
NEW YORK

Out of an income of less than $1,000 a year, the average urban family of five in most large American cities has to spend from 40 to 50 per cent of their income for food. Undoubtedly an important factor contributing to this large percentage is the cost of municipal food handling and distributing, as was indicated by a recent study in New York City, where it was ascertained that about 37 cents out of every consumer's dollar went for the cost of municipal food transportation. Public markets are considered by many an essential factor in combating the high cost of foods resulting from the present individualistic methods of municipal food handling. The past few years have seen many experiments along market lines, either under public, semipublic or private control, either temporary or permanent in character. It would seem that the most effective results might be expected with the highest degree of municipal control, including a regulation of rents, or retail food prices and consequently of profits. Obviously, if a public market is properly situated, it can effect still further economies to the consumer by the elimination of the cost of delivery and the loss resulting from the operation of the stores on a credit basis.

The establishment of public markets, especially when of a temporary and experimental character, introduces into the community life many problems of intimate sanitary and hygienic importance, problems which the public market has in common with the retail store to a large extent. Concentration, however, of retail business in certain areas, possibly under one roof, increases the magnitude of the problem and at the same time enhances the directness and simplicity with which a sanitary control can be established. In any event, whether under private or public auspices, any municipality must meet the responsibility of establishing and maintaining adequate sanitary and hygienic regulations in connection with the city's food distributing system.

Sanitary food control is of interest from several points of view. In the first place, there are the representatives of the municipality, usually the health department officials, who have the responsibility of inspection and law enforcement. Of great significance in this connection are the recent findings of health departments, perhaps especially the New York City department of health, to the effect that intelligent, educational inspection is tremendously more efficient, from the point of view of accomplishing results, than is any amount of uninstructive visiting, legal prosecutions and insignificant fines.

Further, the dealer himself is intimately concerned in sanitary law compliance. It is essential that he should be made to realize the economic importance of sanitary food protection and waste prevention, in addition to the health hazards of careless food infection.

Finally, there is the consumer, the purchaser, who is interested in food protection and desires food protection, aroused to the necessity by motives of disease prevention, cleanliness, decency, and estheticism.

From whatever point of view the problem is approached, however, those interested soon realize that the special problems of market sanitation are, in the main, three in number. In the first place, because of the perishability of ordinary food products, and because of the risks of disease transmission, there are dangers of contamination and possible infection, by means of dust, dirt, flies and dirty fingers. It is certainly conceivable that tuberculosis, typhoid fever and other diseases may be, and perhaps frequently are, transmitted in this way. Further, there are the special dangers of decomposition, the rare development of genuine ptomains, the more frequent pathologic bacterial infections, etc. Finally, there must be mentioned the comparatively insignificant hazards resulting from adulterated or preserved foods, a problem in fraud prevention largely of economic, rather than of sanitary, significance. Such a classification does not, of course, include certain other possibilities, such as the presence of natural poisons, as in mushrooms, the presence of animal parasites, as in pork, the development of a specific poison, such as solanin in potato sprouts, and special individual idiosyncrasies, as pathologic reaction to egg protein. It ignores entirely what would seem to be the most important food factor in health conservation, namely, proper dietary food selection, a factor of hygienic rather than of sanitary importance and one which is, therefore, not apropos at this point in the discussion.

To confine the discussion largely to the sanitary aspects, it might, perhaps, for the sake of clearness, be best to adopt a rough classification of the major points in market sanitary control and to discuss these very briefly under the following headings:

PRODUCTS AND THEIR CARE, LABORATORY CONTROL

Chemical Analyses.—It is, of course, possible nowadays to find in most large cities adequate facilities for the chemical study of foods offered for sale in municipal markets, and therefore, more or less under municipal guarantee. Such analyses should be made to detect illegal adulterants or preservatives and to insure protection against the sale of deteriorated or decomposed products.

Bacteriologic Analyses.—Routine procedures of this kind are, of course, essential if milk and dairy products are permitted to be handled in the market. Bacteriologic analyses to detect contamination of foods from various sources may, from time to time, be worth while. Consequently the necessity for municipal equipment to meet demands in this field should be recognized when market plans are being developed.

Calorific Analyses.—This is the type of analysis and check which cities will have to recognize in the future. Eventually governmental authority will have to take the responsibility for food standardization, and if this standardization is to be on a rational basis, calorific values will have to be employed. Further, if the purchaser is ever to be educated to the extent that she can buy her food supply on an intelligent food value basis, there will have to be mechanism for routine, calorific food analyses. In the present state of development an equipment of this kind cannot, of course, be considerered a prerequisite to a market establishment. At the same time, its need should be emphasized, so that in the future it may become an essential part of municipal market control. Again, it must be pointed out that this is, of course, of hygienic rather than of sanitary importance.

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Seventh Annual Session of the American Medical Association, Detroit, June, 1916.

THE STAFF

Living Wage—As Dr Gorgas has recently emphasized, essential to the hygienic welfare of the worker is a sound, economic status It means for the industry a higher degree of intelligence and cooperation from the employees, factors which are essential in the enforcement of the rules of personal hygiene This is perhaps of greater significance in food handling establishments than in almost any other industry

Selection of Healthy Employees—This is of the greatest importance in food industries, if we are to avoid a constant succession of "Typhoid Mary" catastrophes Modern health departments are requiring that food handlers be free from communicable disease The proper place to inaugurate a check is at the beginning of the period of employment This can be done only by an initial medical examination resulting in the selection of healthy employees

Periodic Medical Examinations—This is now being required by modern health departments for the detection of disease carriers or individuals suffering from communicable diseases Here, of course, municipal laboratory equipment is essential for the conduction of Widal and Wassermann tests, the examination of sputums and throat cultures, the bacteriologic study of excreta, etc These requirements are, of course, applicable to small retail food establishments and, indeed, to restaurants, boarding houses, hotels, etc On the other hand, the city, if it maintains municipal markets, has a special obligation for guaranteeing that the food products under its control shall be handled by individuals free from communicable disease

EQUIPMENT AND METHODS

In this field the details are numerous and it is impossible in this paper to discuss them at all fully The major points might be enumerated as follows

It is absolutely essential that there be adequate and sanitary toilet and handwashing facilities for the market and stall employees Hot water, individual towels, and soap from a holder, are essential Toilets should be equipped with automatic flushes, so as to avoid a series of constant contacts Washing facilities should be readily accessible in conjunction with toilet facilities

Food should be protected from animal contamination by at least a 2-foot elevation from the floor

Receptacles with covers should be provided for rubbish and garbage, satisfactory arrangements being made for emptying and cleaning, and the rules of the market should prohibit the cleaning of fowl, the accumulation of refuse, etc

Adequate refrigeration is essential This applies to storage refrigeration facilities in conjunction with the market, and to special refrigeration for local stall ice-boxes, or for enclosed display cases The proper draining of ice-boxes, especially in case ice is used for refrigeration, is required by practically all market codes

The laws regarding spitting should be strictly enforced

Most municipal ordinances require that food establishments should be properly screened from flies during the fly season In addition, it is usually required, to quote the sanitary code of New York City, that "no food intended for human consumption should be kept, sold, offered for sale, displayed or transported unless protected from dust, dirt, flies and other contamination" This is usually interpreted to apply particularly to foods eaten without being cooked or peeled

Efficient janitorial service, with an arrangement with the stall occupants for cleaning, is necessary if decency is to be maintained

Public markets, particularly when under municipal control, should take advantage of every opportunity, by the use of placards, leaflets, etc, for the education of the public regarding the dangers of food infection as a result of unnecessary handling, the risk in promiscuous coughing and sneezing, etc

THE BUILDING

Adequate light and ventilation are not only necessary for the physical welfare of the employees, but are tremendous instruments in the maintenance of cleanliness and in increasing the commercial attractiveness of the market

Floors should be impervious, waterproof, properly drained, and maintained in cleanly condition

A plentiful water supply for flushing and other general purposes is absolutely necessary to market operation Incidently, in this connection, drinking fountains should be provided for employees and patrons

ADMINISTRATIVE CONTROL

It would seem, judging from experience in many American and foreign cities, that a concentration of authority and responsibility is an asset in the operation of municipal markets This implies the establishment of a market department or at least of a market division in an existing department The necessity for coordination in this field is most strikingly illustrated by the administrative situation arising subsequent to the establishment of the temporary curb markets in New York City a year or more ago While these markets were established by the borough president's office, on street area under the control of that office, a superficial survey of the diffusion of responsibility indicated that in addition to the borough president's office there were also concerned, from diverse points of view, the department of health, the department of street cleaning, the department of water supply, the department of docks and ferries, the bureau of licenses and the department of police Certainly if New York City is to take further steps in the direction of municipal market development, a concentration of authority is essential From the point of view of sanitary control, there can be no doubt that responsibility should rest with one office, rather than be distributed as was the case in New York City, where the health department inspectors were supposed to enforce the rule regarding food protection, the street cleaning department provided janitorial service of a kind, the borough president's office was responsible for cleanliness as regards the toilet facilities, etc

Historically, most cities attempting to deal with the necessity for municipal retail markets have paid some attention to the economic aspects of the situation, have attempted to control prices in a greater or less degree, but have, to a large extent, ignored the necessities for special sanitary regulations and particularly for specific education measures in food hygiene The markets of Philadelphia and Baltimore, while attractive structures, and while apparently serving a useful purpose, by no means take full advantage of the opportunities for food control and food education In this field, so far as the observations of the author are concerned, the city of Cleveland is unique The Euclid Avenue Market in Cleveland in addition to being a model establishment from the point of view of construction, light, ventilation, refrigeration, food protection, and toilet and hand washing facilities, has taken advantage of many opportunities for educating the consumer along lines of food sanitation Of course even in this market much remains that could be done in increasing popular knowledge regarding food selection, the economies of food purchasing, and the essentials of food care in the home

In conclusion, it cannot be too forcibly emphasized that in modern public health work, and particularly in the field of food sanitation, we are at the point where we are ready to drop the word "public" and to talk primarily about health Paradoxical as it may be, the keynote of modern sanitation, and especially food sanitation, is personal hygiene This means personal cleanliness From the point of view of disease prevention it is undoubtedly of much greater importance for any city to teach its food handlers to wash their hands before they eat than it is for that city to solve its sewage disposal problem, even though it may maintain an indecent and unesthetic crude disposal by river dilution From a health point of view public market control, while it must be founded on a sound, sanitary basis, is to be effected essentially through a program of personal hygiene If eventually municipalities would meet the responsibility of having this program of personal food hygiene include, not only the infection preventive and disease suppressive factors of food protection, but also the positive, health creative, educational factors of dietary food selection, the public markets would then be utilized in something like their full potentiality as creative, social forces

---

ABSTRACT OF DISCUSSION

Dr J N Hurty, Indianapolis The doctor is right in laying emphasis on the fact of personal cleanliness of the food handler One of the best regulations that could be enacted would be to require that food handlers restrain themselves from introducing their fingers into any of the body cavities In this city, and in other cities, too, I have noticed that food handlers in the dairy lunches, for instance, are very prone to introduce their fingers into their noses and into their ears and into their mouths and then handle food with the same unwashed fingers The possibility of disease transmission in such instance is very great and the habit is repulsive and repugnant In Indiana, and especially in Indianapolis, we have spread the propaganda among the food handlers, especially in restaurants and in hotels, that waiters must be instructed to keep their fingers out of their body cavities We had a very severe outbreak of typhoid fever last fall at Lake Wawasee All the typhoid fever at this lake occurred at one hotel The disposal of sewage was not ideal, but was passably good Bath water was pumped from the lake not very far from the bathing place, but the tank was never filled, except at night time when there was no bathing going on The whole outbreak was attributable to a single handler of food a woman who was a typhoid carrier Very shortly after her appearance within twenty days, typhoid commenced to appear She handled the salads and the pastries

Dr John Dill Robertson, Chicago Dr Armstrong speaks of personal hygiene. This is very important and one of the oldest sanitary teachings Moses was one of the world's first and greatest sanitarians and he laid especial emphasis on personal hygiene He made it a fundamental rule that no man could offer up a prayer to God until he had washed his hands This must have been a custom of the Egyptians from whom Moses received his education and training This world-old sanitary teaching is no less important today In oyster contamination we have the dirty hands of the oyster shucker, in milk contamination, the dirty hands of a milkman, and so all along the line of food handling

Dr Harold B Wood, Charleston, W Va The educational standpoint is the main one on which to develop the food question It is very largely a waste of effort if men are sent into grocery stores and other food establishments to make inspection, if the health officer does not go further back and take up the question with the producer, and with the general public The general public of course, can be reached most effectively through the newspapers which in their progressiveness and their high ideas, are always willing to assist the health officer in instructing the public along these lines The general public should be instructed in what constitutes poor food, what constitutes good canned foods and what swelled cans mean The grocer should not simply be told to send the foods back to the original man, but the canner should be instructed how he can produce better foods Many swelled cans are being sent from one state to another The health authorities of the states should take it up with the canners and teach them that there need be no waste in canned foods if a little more sugar, or, the proper amount of sugar, and the proper amount of heat for sterilization are used Canning clubs are being established throughout the country, and these need public support because they are the educational part in the canning industry of the future But they need supervision, they need sanitary inspection just as much as any other school, and if they are permitted to send out canned foods which spoil before they reach the consumer, as they do in many cases, then the consumer and the general public will turn a deaf ear to the canning clubs and mark them as failures The cooperation that should be urged on the general manufacturer is the labeling of canned foods.

Dr Mary Dunning Rose, New York I visited one of the automobile factories here The noon hour came and the food was delivered to the employees in sanitary receptacles individual sanitary paper mache or paper boxes and cups Farther on we saw men eating with hands filthy black Not one man had made any attempt to wash his hands Then we passed a number of stationary wash basins but not a towel was visible and the basins were dry If they are not teaching factory workers the necessity of washing their hands before they eat, what hope can we have out in the field work to educate the public that they must wash their hands before eating? As to the examining of food handlers, we make a Widal test on a servant either in our homes or in our institutions We find it positive That person is a wage earner of the family, she or he is a menace to the community, and must be isolated if the community is to be safeguarded What are we to do with the dependents? If we find them tuberculous we must isolate them I cannot but feel that the way we have dealt with tuberculosis allowing the consumptive to go free in the community, infecting more and more people, is not intelligent or sensible They should be isolated the same as we isolate smallpox patients The paper urged the examining of our food handlers, but it gave no means to take care of them and to safeguard the community This phase of the problem is important whether it means state insurance for the family, as well as for the sick individual, or federal insurance

Dr W W Tompkins Charleston, W Va. I want to say in reply to Dr Robertson that if we again quote Scripture and from the New Testament we are told that to eat with unwashed hands defileth not a man it is the things that proceed from the heart, from within, that defileth him In this age in which we are now living we must confine ourselves more to modern bacteriologic teaching than quotations from Moses or a greater than Moses in the discussion of modern sanitation

Dr Charles J Hastings Toronto Ont Might I ask a question? How do they determine in New York whether a handler of food is a carrier or suffering from a mild form of some communicable disease? Does the department of health take the responsibility and bear the expenses of the examination, or do they accept a certificate from the family physician, or the physician employed by the employer of the laborer? Those suffering from the milder forms of communicable disease or carrier can get employment that would be perfectly safe, in which they would not be a source of danger, but they should not be employed as handlers of food That might probably be a compromise to help out

Dr Robert T Legge, Berkeley, Calif I understand that in Chicago the food handlers who are employed in some of the large hotels must have satisfactory medical examinations and certificates from the medical men, that the food handlers must be free from communicable diseases and open tuberculous and syphilitic lesions The health commissioner will accept these certificates If we intend to prevent all syphilitic persons from handling food, we would have to deny, I should say, about 50 per cent of the population It is only the persons with open cases of not only syphilis but tuberculosis who should be denied the privilege of handling foods

A REPORT OF AN UNUSUAL CASE OF CEREBRAL MALARIA

OTTO T BROSIUS, M D
PANAMA, R P

In view of the epidemic of anterior poliomyelitis in New York, and the constant travel between that metropolis and Panama, the case here reported is of unusual interest from a diagnostic standpoint because of the several exceptional characteristics it presented

The health authorities of the city of Panama first discovered the case and sent the patient a girl aged 11 years, into Santo Tomas Hospital for diagnosis and treatment Accompanying the patient's admission, a history of illness for two days was given which began Sept 9, 1916 with malaise, headache and chills, and continued with high fever The following day the patient had two convulsions, paralysis of the right side of the body became evident, and she neither spoke nor took any nourishment Communication with any one arriving recently from the United States was denied by the family At the time of onset of the illness the patient was living in Panama, but she had moved into this city, Aug 25, 1916, only sixteen days before the onset of the illness, from the town of Arrajan in the Republic of Panama While there, the family stated, she had several times been stricken with prolonged and intermittent fever and chills

On the second day of the illness a blood smear was sent to the laboratory of this hospital by the health officer of the city of Panama, and the pathologist reported the presence of crescents and many ring forms of mostly the estivo-autumnal parasite, but a few of them showed tertian characteristics Therefore, before sending the patient to the hospital, the attending physician in the city administered 7½ grains of quinin hydrochlorid intramuscularly

The patient was admitted to Dr Preciado's service, Santo Tomas Hospital, Sept 11, 1916, at 11 a m, with a temperature of 38 C (100 4 F), which that same evening rose to 39 8 C (103 6 F) She was fairly well developed, but rather undernourished, and of about normal size for her age She lay on her back with the head a little retracted, her eyes rolling upward, and could not be induced to speak, being in a state of semiconsciousness As much of her family history as could be obtained was negative, and contained nothing of importance

Physical examination revealed the head, scalp, ears, mastoid regions and nose negative The pupils were equal and reacted to light, and were neither dilated nor contracted The neck was found to be quite rigid, and the patient uttered a faint cry when one attempted to bend the neck a little

There were no glandular enlargements The jaws were not rigid and the teeth seemed negative, but the tongue bore a brownish coat

The skin was clean There were present neither jaundice, eruption nor discoloration

The lungs were negative, there was no cough, and the respirations were even, normal in rate, and were not labored

The heart was negative and the pulsations at the wrists were good

The abdomen likewise was negative, and the spleen not palpable

The reflexes were absent at the knees

Kernig's sign of the left side was positive

The right arm and leg showed apparent absolute flaccid paralysis, there was not the slightest motion in either right limb, and when dropped each fell flaccidly as if paralyzed, but there was no difference in temperature between the limbs of the two sides The face gave no signs of paralysis, both sides moved symmetrically

A blood smear was now taken which showed crescents and a very few ring forms, some of which, I believe, were tertian parasites because of the increased size of the erythrocytes, and the more or less characteristic features of the organism,

A lumbar puncture was done next The fluid was found not to be under pressure, and was absolutely clear The cell count showed 5 to the cubic millimeter The pathologist gave a report negative for organisms

On admission, 2 grains of calomel, followed by 1½ ounces of magnesium sulphate and 10 grains of quinin were given by mouth Four 10-grain doses of quinin were administered daily for the first three days, and after that the quinin was reduced to 10 grains three times a day until discharge

September 12, the second day in the hospital, the patient's temperature dropped rapidly from 38.8 C (101 8 F) to 36 8 C (98.2 F), and remained subnormal for sixteen hours To our surprise the supposed hemiplegia had disappeared, though the limbs affected were still quite weak, and the child seemed brighter In the afternoon the student nurse reported two *slight convulsions*, which she described as clonic Accordingly, bromids were given

At this time the urine and stool examination yielded negative results

The white blood count was 12,800

DIFFERENTIAL WHITE BLOOD COUNT

	Per Cent.
Polymorphonuclear neutrophilic leukocytes	70
Polymorphonuclear eosinophilic leukocytes	0
Transitional leukocytes	1 5
Mast cells	0 5
Large mononuclear leukocytes	3 5
Lymphocytes, large and small	24 5

During this count of 200 cells, only one crescent and one estivo-autumnal ring were found Erythroblasts, achromia, polychromatophilia, poikilocytosis, anisocytosis, and basic stippling were not present

The hemoglobin was 68 per cent, and the red blood count 4,240,000, making a color index of about 0 81 plus

While the blood was being taken for examination, a tendency to coagulate with unusual rapidity was noted

September 13, the patient's third day in the hospital, there was a rise of the temperature to 37 6 C (99 7 F), which soon dropped again to subnormal and remained there during the remainder of her stay in the hospital

Because the neck still remained rigid, another lumbar puncture was done, but it likewise yielded negative results The right limbs had acquired more power, and the patient showed marked improvement

September 14 and thereafter there was almost absolute improvement The child became bright and talkative, the temperature remained normal, the pulse became slower, and normal strength was regained in the limbs once thought to be paralyzed Another urine, stool and blood smear examination gave negative results

According to Manson, cerebral malaria was at first supposed to have been caused by the malarial pigment, which formed thrombi in the cerebral veins, but later investigation gave emboli formed by the parasites as the etiologic factor in this condition Accepting this explanation, it seems rather unusual that these should have occurred only on the left side in this case

The prognosis is of course very good for this attack, but experience teaches us that patients harboring the gametes within their blood are always subjected to repeated subsequent attacks of the disease Tremendous doses of quinin have been unsuccessfully given in this hospital with an attempt to destroy these sexual forms, and even salvarsan has failed to produce the desired result

Santo Tomas Hospital

DISINFECTION OF WAR WOUNDS BY THE CARREL METHOD

AS CARRIED OUT IN AN AMBULANCE AT THE FRONT *

H H M LYLE, MD

Professor of Clinical Surgery, College of Physicians and Surgeons of Columbia University Attending Surgeon St Luke's Hospital Late Chirurgien Chef Ambulance d'Annel Oise France

NEW YORK

The Carrel method of disinfecting wounds is based on the following conception To render an infected wound sterile it is necessary to employ a suitable antiseptic in such a manner that the chosen antiseptic comes into contact with every portion of the wound, that the antiseptic is maintained in a suitable concentration throughout the entire wound, and that this constant strength is maintained for a prolonged period If these conditions are fulfilled, every wound will show its response to the treatment by the diminution and disappearance of its micro-organisms

The chemical destruction of the micro-organisms of a wound depends on the difference of resistance existing between the tissues involved and the bacteria present on their surfaces Practically every surgeon will acknowledge the fact that the usual routine application of powerful antiseptics will not sterilize an infected wound "The success of the Carrel method which enables us today to make an infected wound sterile is not due to any miraculous properties of any new drug It must be attributed to a combination of processes which permit the employment of antiseptic substances determined under such conditions of concentration and of duration that their action becomes efficacious These processes constitute a method in which all the details are interdependent It would be impossible to alter the antiseptic without changing its mode of employment Equally, a modification in the technic would demand an antiseptic endowed with different properties"

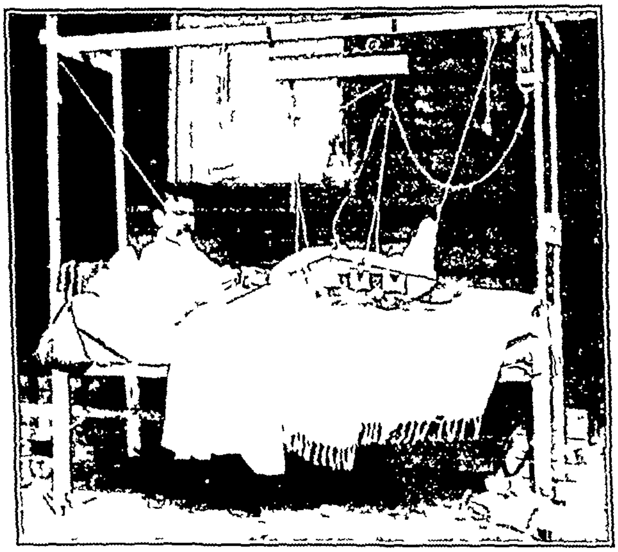

Fig 1—Balanced suspension treatment with method of conveying Dakin's solution to the distributing tubes It is comfortable and greatly simplifies the dressings

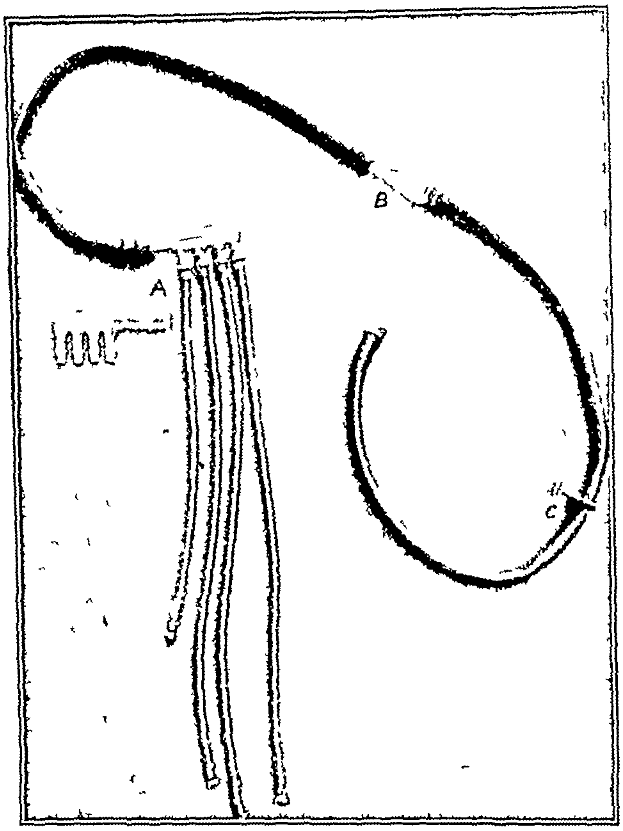

Fig 2—*A* rubber instillation tubes with ends tied and lateral perforation size 18 French attached to a four way glass connection *B* glass drop by drop connection *C* adjustable clamp for controlling the flow

The antiseptic employed is Dakin's *sodium hypochlorite*, 0.5 per cent It is an ideal isotonic wound antiseptic of high bacterial activity and low toxic or irritating quality The latter feature distinguishes it from Javelle water, Labarraque's solution, etc The hypochlorites of commerce are of inconstant composition and generally contain free alkali or free chlorin Such substances are irritating, and when used in moderate concentration may produce very unfavorable results In addition to being a strong wound bactericide, Dakin's solution, because of its pyocytohemolytic powers, has the great clinical advantage of being able to dissolve pus, old blood clots, tissue debris, etc The living tissues resist this dissolution, owing to the protection afforded them by the sodium chlorid of the serum

OPERATIVE TECHNIC TO PREPARE THE WOUND FOR THE INTRODUCTION OF THE ANTISEPTIC

The future course of the wound is directly dependent on the thoroughness of the first surgical act This should be carried out under the strictest aseptic precautions and at the earliest possible moment It consists of a thorough, methodical, mechanical disinfection of the wound with the extraction of all shell fragments, particles of clothing, dirt, etc

---

* Read before the Surgical Section of the New York Academy of Medicine Oct 6 1916 the paper being illustrated by colored photographs (Lumiere) showing the wounds and their progress

* A rather full description of the method of preparing Dakin's solution has been omitted since a similar description was recently published in The Journal. It will appear in the author's reprints

The operative field is painted with tincture of iodin, and the bruised and necrotic skin edges of the wound are trimmed away with a sharp knife The knife and forceps are then put aside With new instruments the wound is laid open like a book and gently explored for shell fragments, pieces of clothing, pockets, etc Everything that could have been infected by the traumatism, or could become the source of infection, is removed All noninfected tissues, and tissues unlikely to become infected, are preserved

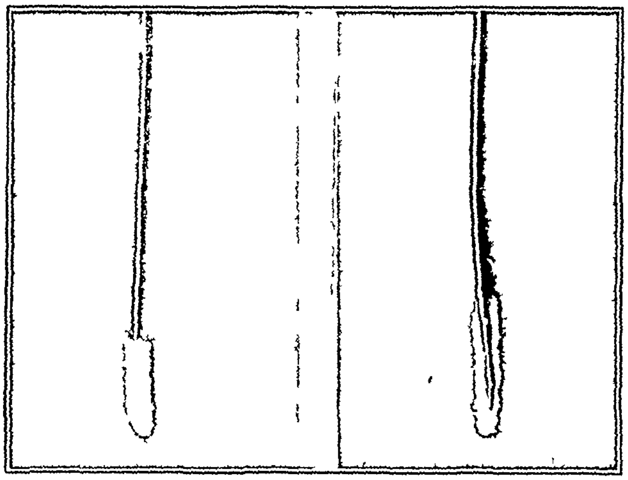

Fig 3—Perforated tube tied at end and dressed with toweling on right, portion of toweling cut away to show lateral perforation

Gentleness of manipulation is the keystone of the technic Brutalization of the traumatized tissue is a technical crime In many of the cases it will be found that fibers of clothing, dirt, grass, etc, are encrusted in the muscular surfaces of the wounds To avoid overlooking this blood-stained debris, the tract of the projectile must be lightly but methodically resected Great conservatism is exercised in the removal of comminuted fragments of bone The same minute and careful mechanical *cleansing is carried out* in osseous wounds as in the soft parts Before placing the instillation tubes a careful revision of the wound is made, and particular attention paid to securing a perfect hemostasis Muscular tissue infiltrated with blood is difficult to disinfect There is another reason special to the employment of Dakin's solution which calls for a thorough hemostasis Owing to its hemolytic property, Dakin's solution has the power of dissolving recent blood clots A poor hemostasis invites the danger of a secondary hemorrhage

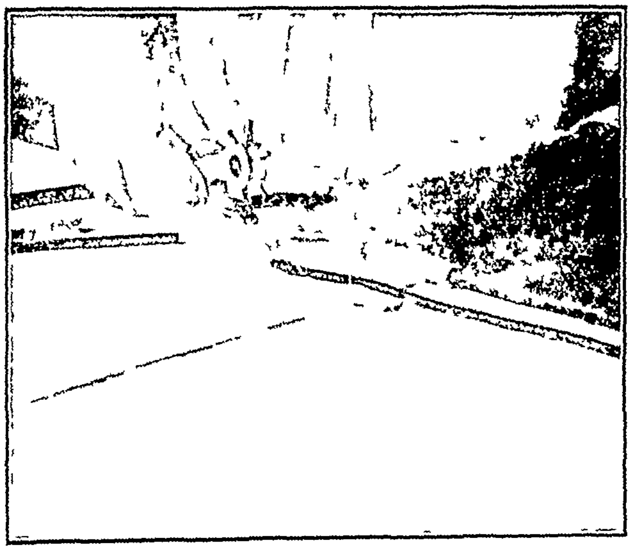

Fig 4—Punching of the lateral holes in the instillation tubes and the prepared dressed tubes

Counter openings for drainage are rarely employed If the necessity for their use should arise, one should avoid making them at the most dependent point, as the goal of technic is to keep the liquid in contact with all the surfaces of the wound

THE INTRODUCTION OF THE INSTILLATION TUBES

The guiding principle is to place the tubes so that the liquid will come into contact with every portion of *the wound The placing of the tubes will vary with* the nature of the wound

Superficial Wounds—A thin layer of gauze is placed over the wound, and on this the requisite number of instillation tubes The tubes are secured to the wound edges by a rubber cuff and suture, or a two-way-flow tube (Fig 5) is used If the tubes are placed directly on the surface they become encrusted, and the orifices are blocked with granulations Too thick a layer of gauze should *not be used, as it will be*come clogged with the wound secretions and prevent the solution from reaching the wound

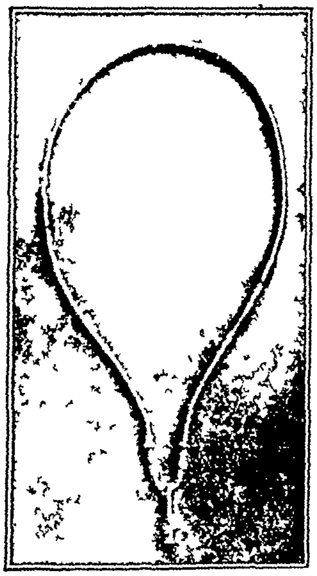

Fig 5—Perforated two way flow tube with connecting tube and rubber cuffs for suturing to the edge of the wound

Penetrating Wounds—In the simple type, a tube without lateral perforations is introduced to the depth of the cavity and the solution allowed to well up from the bottom In a large tract terminating in a cavity with irregular collapsible walls, a little gauze is introduced to support the walls of the cavity and allow a more thorough penetration of the fluid Penetrating wounds with the point of entrance in a dependent position (as the buttock, posterior surface of the extremities, and the back) are treated with perforated tubes dressed with toweling (Fig 3) These dressed tubes keep the antiseptic in contact with the wound A suitable nonperforated tube can also be used

Through and Through Wounds—A perforated tube with the tied extremity uppermost is passed from the lower to the upper wound The liquid, escaping through the small lateral holes, flows back along the tract to the inferior orifice, moistening the entire wound

Wounds of the hand or foot, open amputation stumps, etc, are immersed in Dakin's solution for from ten to fifteen minutes every two hours until *the wound is sterilized* The skin is protected by smearing it with sterile yellow petrolatum

THE AFTER-CARE OF THE WOUNDS

The materials used are described above In the care of the wounds a strict instrumental technic is employed, the gloved hands never coming in contact with the wounds or dressings

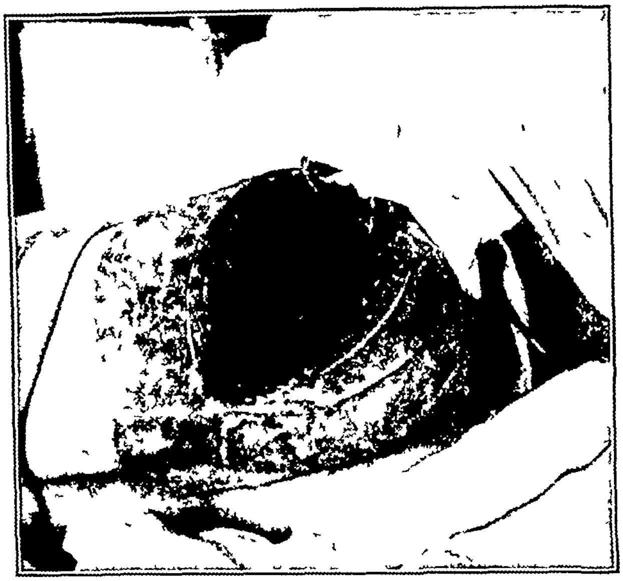

Fig 6—Large shell wound of the buttock exposing the sacrosciatic notch The necrotic edges and the surface of the muscles have been resected and the wound is now ready for the placing of the instillation tubes Gauze impregnated with yellow petrolatum protects the skin

Instillations of the fluid are made every two hours by releasing the adjustable clamp (Fig 2 *C*) controlling the flow The amount of solution employed varies with the nature and extent of the wound, for the average wound, 10 c c are sufficient This interrupted instillation is kept up until the wound is proved sterile The tubes are then removed and a compress moistened with Dakin's solution is applied Formerly a continuous instillation was the method of choice, if used at all it should be discontinued in from twenty-four to forty-eight hours The rate of instillation is from 5 to 20 drops a minute, according to conditions The object is to moisten the wound surfaces and not flood the bed

Once a day, oftener if necessary, the wound, the tubes, and the flow of the liquid are inspected Flushing the wound shows if the solution is being delivered as planned, and mechanically washes away the excess of wound secretion

The Carrel method is not a continuous irrigation It is a mechanical attempt to deliver an antiseptic of definite chemical concentration to every portion of a surgically prepared wound and to insure its constant contact for a prolonged period

PROTECTION OF THE SKIN

In order to protect the skin from the liquid which may accumulate in the dependent portion of the dressing, gauze impregnated with yellow petrolatum is applied to the skin surfaces below the wound (Fig 6)

BACTERIOLOGIC CONTROL OF THE WOUND

This consists in a regular determination of the number of microbes on the wound surfaces This is done by transferring with a standard loop a portion of the secretion to a slide and counting the number of microbes per microscopic field This is carried out every second day, and the results are entered on a suitable chart When the microbes are absent from the wound on three successive days, the wound is considered sterile Though not absolute, the bacteriologic control is of great practical value as a therapeutic guide

The determination of the cellular elements of the exudate, if taken along with the bacteriologic control, gives valuable information For the first six days the exudate is essentially composed of polynuclears and enormous numbers of bacteria Toward the sixth day the polynuclears tend to disappear and are replaced little by little by the mononuclears At the same time the bacteria are diminishing After the tenth day the macrophages appear, and only a few bacteria are found incorporated in the phagocytes The appearance of the macrophages in the exudate is a favorable sign, being a forerunner of the approaching asepsis[1]

A bacteriologic examination of the wound on the entrance of the patient to the hospital is, as a rule, negative The charting of this finding would give a false impression because the germs are undoubtedly present, but the difficulty is in securing a smear from the infected area It is better to begin the bacterial chart one or two days after the reception of the patient As a rule the germs begin to appear after the ninth or tenth hour There is an initial rise on the second or third day This remains so for a few days, and then the descent begins Wounds of the soft parts are sterilized in from five to eight days Greatly traumatized wounds require a longer time Fractures can be sterilized in from two to four weeks If sequestrums are present, they must be removed to obtain an asepsis

Wounds sterilized by the Carrel method are readily reinfected if the treatment is stopped

Reunion of Wound—When, on three succesive days, the bacteriologic control shows the wound to be sterile, it is closed by careful layer sutures In the favorable cases this can be done on the fifth day The average time for the soft parts is from seven to nine days

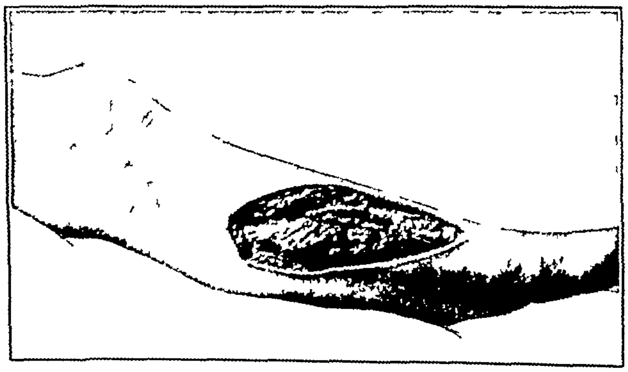

Fig 7—Shell wound of the soft parts of the leg with extensive loss of skin All the traumatized tissue has been resected and the wound treated by the Carrel method

In cases in which sutures cannot be employed, the wounds are closed by adhesive straps passed in such a way that, besides pulling the edges of the wound together, they make a compression around the whole circumference of the limb

For extensive wounds two Canton flannel bands are prepared, the length to be slightly longer than the wound, the breadth to be a little less than half the circumference of the limb On the hemmed edges, shoe hooks are inserted every 2 cm The limbs are painted up to the edges of the wound with a resin, varnished, and the woolly side of the Canton flannel applied One should wait until the traction strips are firmly adherent before lacing them with rubber bands The tension of the rubber bands rapidly draws the wound edges together

---

[1] Depage A Du controle bacteriologique comme indication de la suture des plaies de guerre Bull et mem Soc de chir de Paris 1916 42, 1987

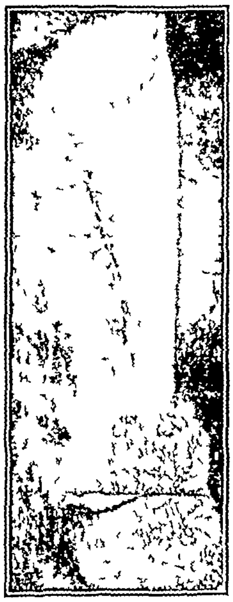

Fig 8 — Secondary sutures result fourteen days later

Wound Healing —The wounds treated by the Carrel technic are entirely different in appearance from those treated by the ordinary methods The Carrel wounds have strikingly bright red vivacious granulations, a minimum amount of mucoid-looking secretion, and no odor There are no redness, no tenderness, no induration in the skin edges The wounds heal with the minimum amount of connective tissue, the scars are supple, the wound edges pliable, and epithelial growth is rapid

RESULTS

In the early months of 1915 I was in charge of Hospital B, American Ambulance This hospital contained 150 beds, and was situated at Juilly, Seine et Marne, 40 miles behind the firing line The wounded were brought from Compiegne in automobile ambulances, arriving in Juilly about twenty-four hours after being wounded This year my experience was gained while surgeon in chief of an ambulance situated 3½ miles behind the firing line

At Hospital B the following procedure was immediately carried out

1 Careful examination of the soldier's clothes to determine the absence or presence of clothing in the wounds

2 Examination and dressing of the wound

3 Localization by Roentgen ray of all bullets, shell fragments, etc , and their immediate extraction The after-treatment was according to accepted surgical principles We were well satisfied with the results obtained, as they compared favorably with those of similar hospitals Today we should consider them failures We had the usual number of pussing wounds, pyocyaneous infections, secondary abscesses, osteomyelitis, joint complications, amputations for infection, delayed healings, etc , along with the worries and uncertainties which are incident to such cases

For the first ten days at the front we followed the old standard methods and the newer physiologic ones Meanwhile we were tentatively trying out the Carrel method At the end of this time the contrast in the results were so striking that we adopted the Carrel method for the hospital

Our experience was that of Depage[1] "The transformation which was established in our results was startling The immediate complications became more and more rare, and suppuration disappeared from our services almost completely" In our service during four and a half months no secondary abscess developed, there was only one case of osteomyelitis, and this responded readily to treatment There were no amputations for infection The average stay for wounds of soft parts was fourteen days, for compound fractures from twenty-eight to thirty-six days

The wounds treated were almost exclusively inflicted by high explosive shells, shrapnel, trench torpedoes, bombs, hand grenades, etc Very few bullet wounds were received

Depage[1] reported his results obtained at the Ambulance de la Panne from June 1 to August as 137 cases sutured, complete union in 112, partial union in 23, failure in 2 cases These figures include 6 wounds of the knee, 12 amputation stumps, 17 fractures, and 102 wounds of the soft parts On the date of August 2, Depage had eighty compound fractures without a drop of pus In August the Ambulance Carrel[2] had closed 450 wounds with only six failures

SUMMARY

The Carrel method is not a continuous irrigation It is not dependent on the miraculous power of an antiseptic, or on any one feature of the method, but on the combination of the whole It is a method of sterilizing wounds by mechanically delivering an antiseptic of definite chemical concentration to every portion of a surgically prepared wound and insuring its constant contact for a prolonged period The progress of the sterilization is rigorously controlled by the microscope Gentleness, thoroughness, and attention to detail are essential for success I firmly believe that the adoption of this method is destined to save many lives, to reduce the gravity of the mutilations, and allow the rapid return to the front of many men who would otherwise be lost to the service of their country

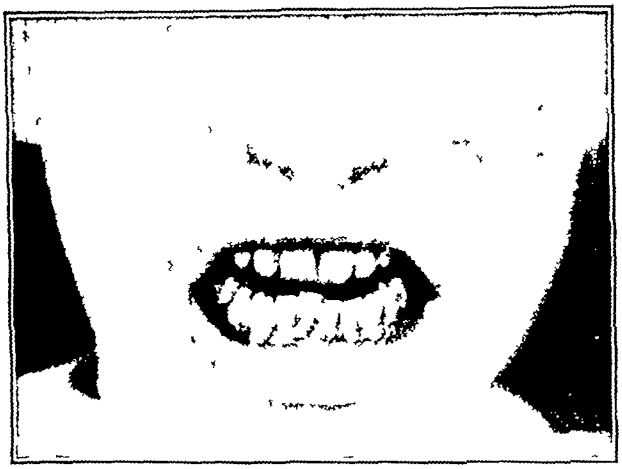
2 Carrel, A Personal communication to the author

Intellectual Ignorance —Ignorance, which in all matters of morals extenuates the crime, is itself, in intellectual matters, a crime of the first order —Joubert

BISMUTH POISONING FOLLOWING BISMUTH PASTE INJECTION

ELLIS B FREILICH, M D
Resident Physician Cook County Hospital
CHICAGO

In 1912, when Mayer and Baehr[1] reviewed the literature of bismuth intoxication following the local application of bismuth to granulating surfaces, they collected reports of sixty-four cases of poisoning with twenty-four fatalities Since that time there have been four cases of bismuth poisoning reported with two deaths



Bismuth deposit on margin of gum adjacent to teeth

The fact that there have been so few cases reported in the last few years, although the bismuth treatment has been used extensively, may indicate that, with improved technic and greater care in its use, the occurrence of this complication has become rare, or else instances of mild intoxication have not been recognized

Dr Beck[2] says, "The occurrence of this accident has deterred many surgeons from employing the bismuth treatment, and since poisoning can be avoided, it would be deplorable that an otherwise useful method should not be employed on this account" That toxic results cannot be entirely avoided is shown by Beck's admission[3] that in 30 per cent of his cases there has been pigmentation of the gums The report of sixty-eight cases with twenty-six fatalities serves to show the existence of individuals who have an idiosyncrasy against bismuth and are susceptible to its absorption with toxic effects

In the case described below, the precautions and technic in the injection of the bismuth paste as advised by Dr Beck were carefully observed and yet poisoning followed, indicating the unmistakable action of bismuth on a susceptible individual

REPORT OF CASE

F D man, aged 22, had been well up to Jan 10, 1916, when he developed an abscess of the left thigh above the knee This was opened at the Cook County Hospital and the patient went home returning in about eight weeks with an abscess of the left hip This was opened, April 19, pus evacuated, and a drainage tube inserted The sinus discharged for about three months July 18, 2½ ounces of bismuth paste were injected into the sinus There was no discharge and the patient went home to see some friends six days later

On the eighth day following the injection, the patient returned to the hospital complaining of soreness of gums and tongue Examination of the mouth revealed a line of bluish-black pigmentation about 2 to 3 mm in width along the border of the gum adjacent to the teeth of the upper and lower maxillae The tongue was swollen, and the pigmentation extended along the under surface of the tongue following the course of the ranine veins On the buccal mucosa, most marked on the right side, were discrete as well as confluent spots of a similar character The glossitis and gingivitis became more severe, and the salivation was so pronounced that the patient lay with his mouth over a basin to catch the flow of saliva He also complained of diarrhea and weakness, but his general condition appeared good The temperature was normal and examination of the blood was negative Urinalysis revealed a heavy cloud of albumin and many granular and hyaline casts

The sinus was irrigated with warm olive oil and the bismuth removed following which the stomatitis subsided, although the pigmentation on the gums and tongue still persist

A CASE BEARING ON THE FUNCTION OF THE PITUITARY BODY

WILLIAM BOYD, M D, M R C P (EDIN) DIPL PSYCH
Professor of Pathology University of Manitoba
WINNIPEG, CANADA

The pituitary body consists of two distinct parts, differing in development, in structure and in function In this respect it bears a close resemblance to the suprarenal glands The anterior part of the pituitary is developed from an invagination of the pharynx (Rathke's pouch), it is glandular in structure, and its function is that of a regulator of skeletal growth and sexual development It is possible, moreover, that it may exert some influence on body temperature, for Cushing[1] points out that a rise of temperature follows

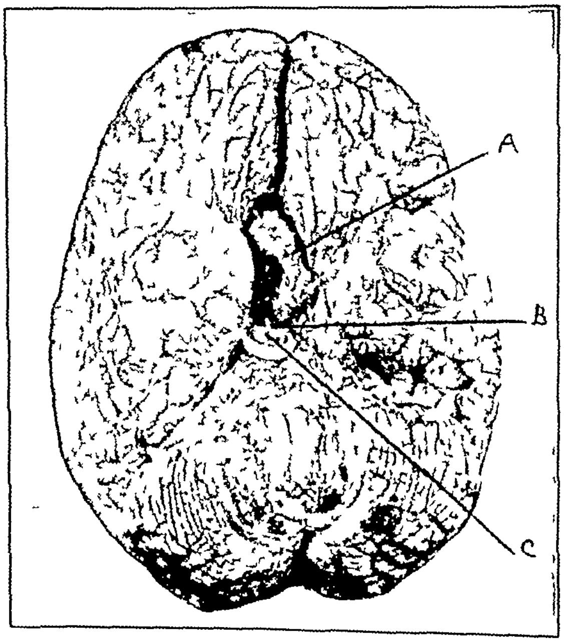

Fig 1—Base of brain showing interpeduncular tumor surrounding infundibular stalk *A* tumor, *B* infundibular stalk, *C* pituitary body

---

[1] Cushing Harvey The Pituitary Body and Its Disorders, p 14

injection of extract of the anterior lobe in cases of anterior lobe deficiency The posterior part, separated from the anterior part by the pars intermedia, is developed as a downgrowth from the floor of the third ventricle, shows in its structure traces of its nervous origin, and has a controlling influence over plain muscle generally, and also over carbohydrate metabolism

There can be no question that the posterior lobe, or possibly its epithelial investment (pars intermedia), produces a secretion of great physiologic activity Injections of posterior lobe extracts produce an extraordinary rise of blood pressure, owing to their stimulating effect on the plain muscle of the peripheral vascular system Moreover, the posterior lobe is known to exert a profound influence on carbohydrate metabolism If a condition of hypopituitarism be induced, either by experimental extirpation of the posterior lobe, or as the result of a pathologic process affecting that lobe, the normal process of glycogenolysis is interfered with, sugars are stored in the body, and there is a resultant accumulation of fat In this condition it is possible for a patient to ingest very large quantities of sugar without a glycosuria being induced Such a condition is described as a high sugar tolerance But the question which presents itself is, How does this secretion, whether internal or external, reach the blood stream? It is in the hope that a little further light may be thrown on this question that the present case is described

The histologic appearance of the nonvascular pars nervosa certainly does not suggest that a secretion is absorbed from it directly into the blood stream The only other mode of such absorption, so far as we know, is into the third ventricle, in which case the cerebrospinal fluid would become the vehicle of the active principle Several facts in our possession suggest that this may prove to be the correct answer

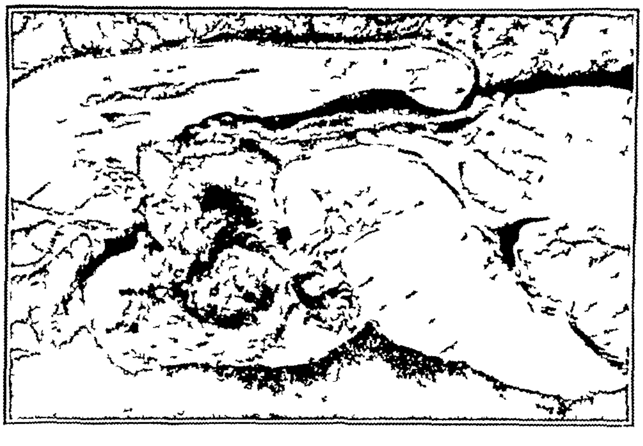

Fig 2 —Sagittal section of brain, showing infundibular stalk emerging from tumor

The infundibular recess of the third ventricle is prolonged for a varying distance into the infundibular stalk, which connects the hypophysis with the tuber cinereum In some animals this prolongation extends right into the posterior lobe, so that any secretion produced by that lobe can readily pass into the third ventricle If in some cases this is the normal course, it is not unlikely that in all cases it is the only course

In the neuroglial network of the posterior lobe, globules, apparently of a colloidal nature, can be seen if a suitable histologic technic is adopted Herring[2] demonstrated that these globules make their way from the pars intermedia through the substance of the posterior lobe toward the prolongation of the infundibular recess of the ventricle, into which they appear to discharge It is highly probable that this colloid represents the active principle of the posterior lobe

Another link in the chain of evidence was forged by Cushing and Goetsch,[3] who showed that injections of the cerebrospinal fluid produced physiologic symptoms similar to those obtained with posterior lobe extract These observers were successful in producing their results with human cerebrospinal fluid, as well as with that obtained from animals Goetsch[4] further found that by placing a clip on the infundibular stalk in animals he could produce a high tolerance for sugars, thus indicating that the route by which the posterior lobe active principle is absorbed had been interfered with

Finally, in the case about to be described, it will be seen that Nature placed a ligature in the form of a glioma around the infundibular stalk, thus cutting off access to the third ventricle, with the result that a high sugar tolerance was produced

History—A well developed boy of average height and weight, aged 10½ years, in February, 1915, began to suffer from slight attacks of frontal headache, occasionally accompanied by vomiting These, however, were never serious enough to prevent him from attending school At the same time he complained to his father that he was able to see only one half of the clock He was seen by Dr Harvey Smith, who found that vision in each eye was normal, and that no refractive errors or structural changes could be detected

Physical Condition—In September, 1915, he again consulted Dr Harvey Smith, now complaining of defective vision The ocular condition was found to be vision, right eye, 20/70 unimproved with glasses, left eye, only very feeble light perception Distinct exophthalmos was present The pupils were larger than normal, and reacted sluggishly to light and accommodation There was less reaction when light was thrown in obliquely from the temporal side No field of vision could be obtained in the left eye In the right eye, temporal hemianopsia existed with reversal of the color fields The retinal vessels were dilated and tortuous, the edges of the disks a little hazy, and the surface of the disks injected These changes were more marked in the left than in the right eye

The case now came under the observation of Dr Chestnut The eye symptoms naturally directed attention to the pituitary region A roentgenogram of the sella turcica was taken, which showed slight enlargement of the sella, but thinning of the bony walls The tolerance to sugar was tested and was found to be markedly increased, there being a negative result to 250 gm. of levulose There was no polyuria, and the urine was normal The systolic blood pressure was 110 Extract of the anterior lobe of the hypophysis was injected, but without producing any thermal response This, together with the absence of skeletal and sexual changes, suggested that the lesion was probably one involving only the posterior lobe

The eye symptoms, probably beginning with bitemporal hemianopsia, the high sugar tolerance, and the apparent enlargement of the sella turcica, all suggested a tumor of the pituitary body, and the patient was referred to Dr Harvey Cushing of Boston, who concurred in the diagnosis Dr Cushing operated on him by the transphenoidal route Oct 29, 1915

At the operation, notes of which were kindly furnished by Dr Cushing, "a soft, translucent struma began to extrude itself from the small incision in the sella floor As much of the growth as was thought justifiable was removed"

[4] Goetsch E Cushing, Harvey and Jacobson C Carbohydrate Tolerance and the Posterior Lobe of the Hypophysis Cerebri Bull Johns Hopkins Hosp 1911 **22**, 165

Subsequent History—The patient returned to his home two weeks after the operation, and remained well, although with no apparent change in the eye condition, until the evening of November 21 He then had an attack of vomiting, and complained of severe headache Seen by Dr Chestnut on the following morning, he was in a semicomatose condition with a temperature of 102 F, pulse of 100, and evident signs of cerebral irritation and increased intracranial pressure He remained thus all day, but during the night had several convulsions, and sank into a condition of coma with modified Cheyne-Stokes breathing Death occurred on the morning of November 23

Postmortem Examination—Permission was obtained for examination of the head only The cranium was not unduly thinned There was no flattening of the cerebral convolutions, nor any excess of cerebrospinal fluid The sella turcica was a little wider than usual, but of normal depth The pituitary body appeared' normal, and lay free in the sella It was removed together with the brain On the inferior surface of the brain, in the interpeduncular space, and apparently growing from the region of the floor of the third ventricle, there was a large, soft, grayish mass, which was at first mistaken for a tumor of the pituitary body The left optic nerve was embedded in the mass But the most important indeed, the essential feature of the case was the fact that the infundibular stalk was completely surrounded by the tumor, passing right through it, and being apparently constricted by it It was as if some ingenious experimentalist had placed a ligature round the stalk in order to determine the effect of such a procedure The involvement of the stalk was even greater than appears in the accompanying illustration On removing the brain and inspecting the floor of the sella turcica, one could not but admire the precision and perfection of the operative approach The clean oval opening lay in the very center of the fossa, and exactly underneath the pituitary body

Microscopic Examination—The tumor is of an open reticular structure In the meshes of the network there are considerable accumulations of hyaline material The cells, which are large and round or oval, show in places a definite syncytial arrangement Here and there are blood spaces, showing marked dilatation and engorgement Specimens stained with phosphotungstic acid hematoxylin show coarse neuroglia fibers There is no sharp line of demarcation between the tumor and the brain substance The growth is an example of a glioma Except for some increase in the number of eosinophil elements, the pituitary body shows no evident abnormality

SUMMARY

1 The patient displayed symptoms of pituitary posterior lobe deficiency, in addition to pressure "neighborhood" symptoms

2 There was no evident pathologic lesion in the pituitary body itself

3 A tumor encircled the infundibular stalk, thus interfering with any communication which may normally exist between the posterior lobe and the third ventricle

4 It seems not unreasonable to regard this case as an additional argument in favor of the theory that the secretion of the posterior lobe of the pituitary passes by way of the infundibular stalk into the third ventricle

INNOMINATE ANEURYSM WITH RUPTURE

REPORT OF A CASE WITH TUBERCULOSIS OF ADJACENT TISSUES

RENÉ BINE, M D
Assistant in Medicine University of California Medical School
SAN FRANCISCO

The arteries usually affected by aneurysm are, in the order of frequency of involvement, the thoracic aorta, the popliteal, the femoral-iliac, the carotid, the subclavian, the innominate and the axillary[1] Aneurysms of the innominate are in themselves sufficiently rare to warrant recording their occurrence The case about to be described presents, however, two additional features of unusual interest (*a*) tuberculous involvement of the tissues adjacent to the arterial wall, and (*b*) external rupture of the aneurysm Innominate aneurysms very seldom fill with clot and heal spontaneously More often they gradually increase in size They seldom perforate into the trachea, pleura, mediastinum or a vein Still more rarely do they perforate externally[2]

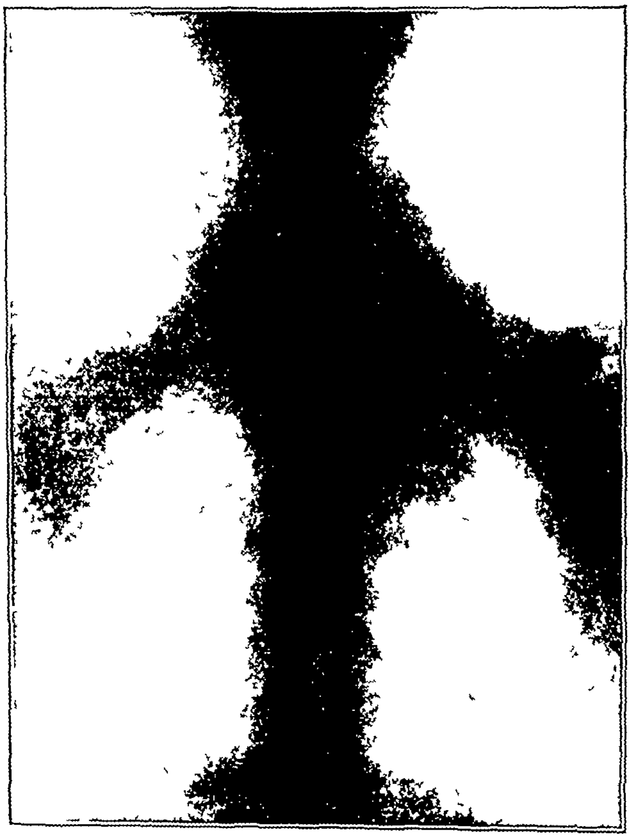

Fig 1—Roentgenogram taken in October, 1911 The enlarged innominate gives a definite shadow It was thought that the aorta too, was involved, the necropsy disproved this

Tuberculous disease of arteries is in itself rather a frequent lesion, vessels being affected by inoculation with bacilli carried to them from distant points, or by direct extension of the process from adjacent foci Numerous cases have been reported as proof of the former method In some of them the arterial disease is a part of a general, acute miliary tuberculosis, in others there is a chronic tubercle of a large artery, such as the aorta, this being occasionally followed by an acute miliary tuberculosis, presumably arising from the chronic lesion[3] The second method is by far the more common, and is often seen in the involvement of arteries in tuberculous lungs Here the process is one of destruction of the external coat and, if the process is a rapid one, aneurysmal dilatation, with occasional rupture and fatal hemoptysis, may occur The process, however, is usually and fortunately a more chronic one, so that from the beginning the inner coat reacts, thickens, and eventually, with or without the aid of a thrombus, leads to obliteration of the lumen Ultimately the thrombosed area may undergo caseous degeneration [4]

[3] Krumbhaar Solitary Tubercle of the Aorta Occurring in a Case of Generalized Tuberculosis Bull Ayer Clin Lab Pennsylvania Hosp 1908 No 5 p 66 (Bibliography to 1908 given)

On the other hand, tuberculous disease of large arteries by direct extension is rare, probably because of the inherent anatomic resistance offered by the elastic fiber present Even in cheesy tuberculous foci it is well known that elastic fibers resist the longest Furthermore, tuberculous glands seldom extend beyond the capsule, and rather tend to mat and form a big mass, with the production of periglandular fibrosclerotic tissue [5]

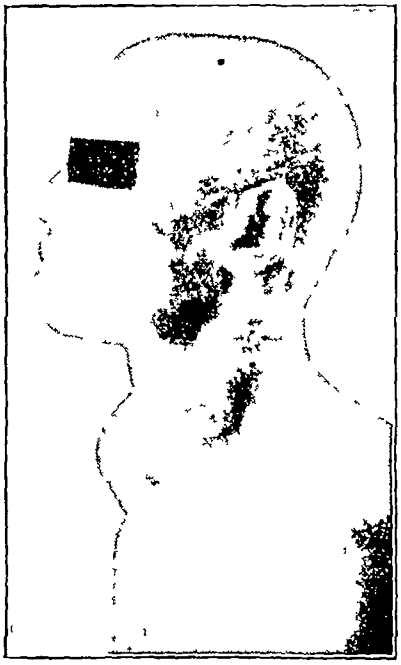

Fig 2 —Side view of patient showing tumor mass arising on the right side but extending to the median line

Tuberculous disease of large arteries being rare, it naturally follows that in the production of aneurysms, tuberculosis can play only an insignificant part As a matter of fact, there is but one case on record in which tuberculosis seems to have been the etiologic factor Curiously enough, in this case the innominate was the artery ~~affected~~ [6] Here the patient was known to have tuberculosis There were no distinct signs of aneurysm, no marked dulness, no pulse differences, and a recurrent paralysis was ascribed to the tuberculosis The patient died of miliary tuberculosis Postmortem examination revealed an innominate aneurysm the size of an egg, almost filled with laminated thrombi Histologic study showed tuberculous disease of the vessel wall, the latter having led to the aneurysm formation

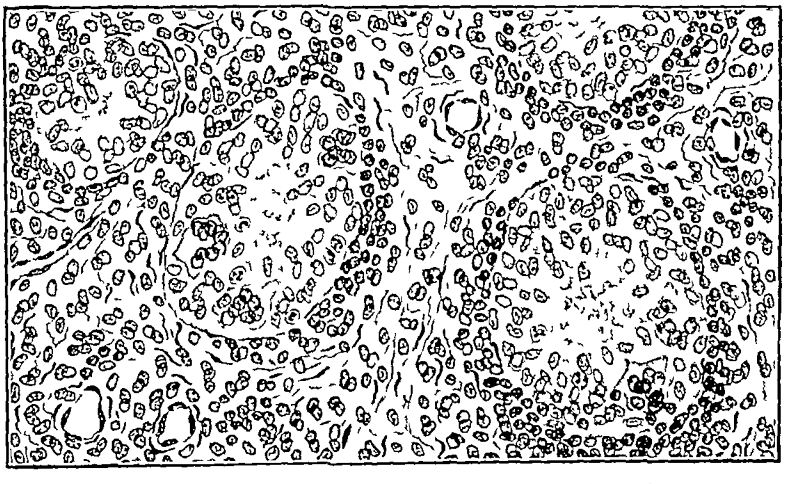

Fig 4 —A drawing of a microscopic preparation made from a biopsy taken ten days before death The tissue was fixed in 10 per cent dilution of liquor formaldehydi, mounted and sectioned by the celloidin method, and stained with hematoxylin and eosin In all three complete miliary tubercles are visible and a part of a fourth The centers of the lesions have undergone caseous degeneration giant and epithelioid cells appear more toward the periphery and the outermost division of the tubercles is composed largely of small round cells

In the following case the aneurysm was undoubtedly the result, not of a tuberculous process, but of syphilitic disease There was a history of untreated syphilis, and the finding of a positive Wassermann reaction There was history of pain over a period of two years before the mass appeared This pain was not of such a character as could be referred to lung or pleura Furthermore, sections made from the arterial wall showed, in spite of its close proximity, no involvement by the tuberculous process

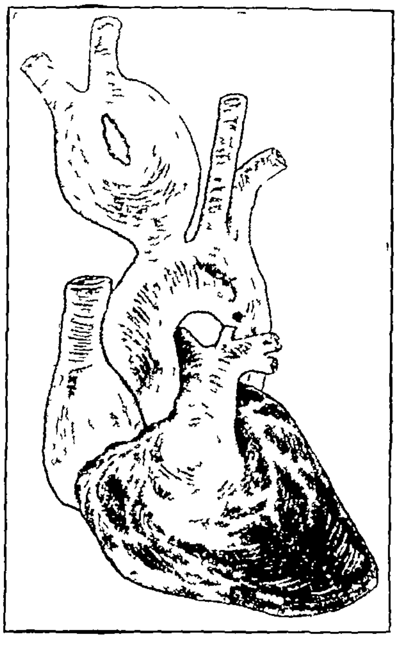

Fig 3 —A drawing of the heart and a portion of the large vessels passing off from it The superior vena cava has been removed in part to facilitate the delineation of the large fusiform aneurysm of the innominate artery The rent in the aneurysmal wall which communicated with the sinus that opened on the cutaneous surface of the body above the inner end of the right clavicle is also shown

REPORT OF CASE

History —F C, man, negro, aged 42 first sent for me on the evening of June 12, 1911, desiring relief from precordial pain He told me that he had an aneurysm and that this diagnosis had been confirmed by Roentgen examination six months previously (in December, 1911, at the Presidio)

For two years prior to this time he had suffered from occasional attacks of pain at first rather localized to the region of the second right costal cartilage, but later of a sharp, lancinating character all through the right side of his chest and at times in the neck and down the right arm and at times he could scarcely raise it March 1, 1911 he had noted the presence of a mass above the inner end of the right clavicle He had no dyspnea except for a short time at the onset of the trouble, no cough, dysphagia or hoarseness

The patient was well developed and nourished, 5 feet 7 inches in height, and weighed 155 pounds He was comparatively comfortable the following morning, and nothing of importance was noted other than what was unmistakably an aneurysm Except for pain subjective symptoms were absent The tumor, which was small, was visible above the sternum, extending just to the right sternoclavicular junction At this time it was thought that the innominate was involved (The examination was not complete and further observations were discouraged by the patient, who felt that more relief was obtained from "Dr Munyon's X X X rheumatism and indigestion cure" than from iodids and from the morphin given for pain)

[6] Weinberger Mitt d Ges f inn Med u Kinderh 1916

In 1890 the patient had had a venereal ulcer for which he had taken medicine for six weeks No symptoms or signs of syphilis had ever followed He had been married ten years, his wife a Filipino, had never been pregnant He had malaria in 1898 in Cuba and tonsillitis in 1909 He was in the United States Army from 1892 to 1900 and then in the quartermaster's department for four years He had never used liquors or tobacco

He was again seen, Aug 3 1911 when he came to have an application for a pension signed He permitted examination of his neck which showed but a very slight increase in size, and stated that he was still taking the XXX and felt fine He was warned as to the danger he was incurring by engaging in active exercise but he evidently paid little heed to the advice He was again seen, October 2, having been several days in bed

Examination—The tumor had increased considerably in size, it bulged and pulsated to such an extent that, with the thinning of the overlying tissues, it seemed almost ready to break through the skin The apex beat of the heart was not heaving, in the fifth space, in midclavicular line A soft systolic murmur replaced the first sound A somewhat rough systolic murmur was audible over the aortic area as well as over the tumor mass The pupils were equal and small, and reacted to light and accommodation The lids were tremulous The skin, sclera and mucous membranes were negative There was no jaundice The tongue throat and gums were negative The thyroid was negative The posterior cervical glands on the left side were palpable, also small left epitrochlear The lungs were negative The abdomen was level symmetrical soft and tympanitic throughout There was liver dullness, fifth rib to costal margin in midclavicular line, it was not palpable The spleen and kidneys were not palpable The penis testes, back and extremities were negative The reflexes were normal

The patient was induced to enter the University Hospital, October 19, where he remained for six days Figures 1 and 2 are from pictures taken during this period Blood examination revealed the Wassermann reaction weakly positive, hemoglobin from 88 to 60 per cent red blood cells 4 800 000 white blood cells, from 9 000 to 7,000, polymorphonuclears, 72, large mononuclears 8 small mononuclears, 18 eosinophils, 2 The systolic blood pressure while the patient was in the hospital was October 19 left 140 mm Hg, October 24, right 94, 1 104, October 26, right 102, 1 114 Urine examination was negative The fundi showed no abnormalities The lids were tremulous

Diagnosis—It was believed that the subclavian was the vessel most involved, and this opinion was shared by all who saw the patient The roentgenogram however, showing apparent involvement of the innominate and even possibly of the aorta frightened off even the most daring of my surgical friends one of whom was at first aching to attempt a surgical cure Attempts to induce clotting, by introducing silver wire, did not appeal to the patient who wanted me to stick in some sort of needle and let out blood, his idea of an aneurysm being that it was a walled off pocket of blood easily drained

After going home, October 27, the patient was pretty comfortable for a while having a dragging pain only when recumbent on either side This became more severe, seemingly aggravated by a gradual softening of the entire mass but relieved by lying flat on his back November 10 on arising in the morning the patient removed the cotton gauze dressing with which he kept the mass covered, and found that perforation of the skin had occurred, then there escaped at least a quart of thin yellowish fluid this being attended by a sense of relief and with no shock There was no blood in the discharge The patient was seen on the following day, and on November 15 was again taken to the hospital where the following notes were made

General condition about the same as on leaving hospital in October Shoulder feels stiff and sore, patient has little use of right arm Practically no pain Weight 138 pounds Hemoglobin 84 per cent , red blood cells, 4,000,000, white blood cells, 9,200, polymorphonuclears, 68, large mononuclears, 10, small lymphocytes, 22 Urine negative

November 20 Since the patient entered the hospital the wound on the neck has been carefully cleansed daily with hydrogen peroxid and packed with small gauze strips with a small amount of camphor-phenol The purulent discharge seems to be decreasing and granulation occurring rapidly Smears were taken today, also a small section of wall of ulcer The tissue is not sensitive and not highly vascular

November 22 Yesterday morning at 5 a m the intern on service summoned to see the patient, who was reported as pulseless after a large hemorrhage found that the patient had been to the water closet a short time previously, and had just fallen asleep when he was awakened by a gush of blood from his neck He was lying in a great pool of blood, on his right side The pulse was weak, but clearly made out Morphin sulphate, 0 015 gm, was given hypodermically The hemorrhage was pretty well stopped of itself at that time, and after preparations had been made for a possible secondary hemorrhage, the dressing was removed and the sinus closely packed with iodoform strips The patient was dizzy, and complained of great thirst He was given plenty of fluids, but no stimulation

November 23 It had been intended to leave in the packing for sixty hours, if possible, but this afternoon at 4 o'clock the patient's temperature rose to 39 C (102 2 F) The packing was removed, the sinus cleaned, and more tissue from the granulating surface removed for injection into guinea-pigs and for staining for tubercle bacilli (See pathologic report below) The artery could be seen pulsating in the floor of the sinus It was covered by a large slough which it seemed best not to disturb The patient suggested that be could at times feel the escape of air in the sinus when he took a full breath The process was undoubtedly in close apposition to the right apex The pulsation seen was probably from the right subclavian artery

Of the tuberculin reactions, the von Pirquet was positive, the Calmette questionable, or very weakly positive if at all, and the Moro negative

November 24 This morning the sinus was unpacked, filled with collargol solution, 5 per cent, sterilized by boiling, and roentgenograms taken The mediastinum was taken obliquely to miss the heart shadow if possible, and an anteroposterior view was taken The patient's condition was good The blood picture showed little effect from hemorrhage Late this afternoon the patient s temperature rose to 39 C (102.2 F) (This seemed to be a part of the febrile course that had been present since the patient entered) He had been constipated to a marked extent, but no more distress was noted in his neck

November 30 The patient s sinus was granulating very rapidly and had decreased to one third its former size It was dressed three times a day The patient complained of increasing tenderness in the right shoulder, extending down inside of the arm to the elbow He believed there was slight swelling of the forearm, though I could not make it out The glands of the axilla were much enlarged and very painful Tincture of iodin and an ice bag were applied locally

Previous to this time the patient had received three injections of a mercury preparation intravenously (November 16 18 and 20) Inunctions of mercury and potassium iodid were given November 25 to 30, inclusive

December 1, 1911 At 3 55 a m the patient had a large hemorrhage further severe ones occurring at 4 30 6 and 7 a m, at which time 700 c c of salt solution with 10 minims of epinephrin were administered intravenously

The patient died at 7 30 a m

Pathologic Report—Necropsy was performed December 1 Rigor mortis was complete Despite the natural pigmentation of the skin, it showed a marked pallor The pupils were regular in contour, moderately and equally dilated Palpable lymph glands were slightly enlarged There were no visible skeletal deformities An irregular sinus opened above the inner end of the right clavicle and led downward and medially, its external orifice measured about 4 by 3 cm., the long diameter being approximately parallel with the upper border of the clavicle. In the neighborhood of the sinus, the tissues showed a considerable degree of tumefaction.

When the thorax was opened and the lungs retracted, a large fusiform aneurysm of the innominate artery was visible. It was firmly adherent to the tissues surrounding the sinus. The heart and large vessels were removed *en masse*. In the aneurysmal sac at its upper and anterior aspect there was a rent which was continuous with the sinus opening above the clavicle. Through this rent an underlying thrombus appeared. The aneurysm measured 7 by 5 cm. and involved the innominate artery throughout its entire extent, but did not include the subclavian or common carotid arteries. The thrombus was of such size as almost to completely fill the cavity of the aneurysm, was easily removed, being attached to the wall of the vessels by very thin adhesions, and on gross section was found to consist of fibrin arranged in a distinctly lamellated manner. The shape and loose attachment of the thrombus was of such a nature that it must have acted during life very much in the fashion of a ball-valve. The chambers of the heart were practically free from blood save for a few small clots entangled in the meshes of the trabeculae corneae. Both the thoracic and abdominal divisions of the aorta evidenced a mild degree of patchy atheroma. The cardiac valves were free of microscopic pathologic changes, which was also true of the circumvalvular and remaining mural endocardium. The foramen ovale was not patent. The coronary arteries were in good condition. The left ventricle was somewhat hypertrophied.

The parenchyma of the apex of the right lung was contracted by several fairly large cicatricial processes, and the visceral pleura of that region as well as the adjacent parietal pleura were studded with miliary tubercles. The tuberculous involvement of the parietal pleura on the right side extended as far down in the midaxillary line as the upper margin of the fourth rib and above it invaded the perisinusoidal areas quite out to the cutaneous limitation of the opening. The left lung was clear of tuberculous lesions as well as the left pleura in its entirety.

Aside from varying moderations of exsanguination the abdominal organs and the external genitals showed nothing of any special pathologic importance. The brain and cord were not removed.

Additional Notes.—Ten days before the patient's death a piece of the wall of the sinus at its external opening was removed for the purpose of microscopic examination and inoculation experiments. The sections revealed typical miliary tuberculous lesions. A portion of the biopsy was triturated in sterile normal salt solution, and of the resulting fluid, 1 c.c. was injected subcutaneously into each of two guinea-pigs, right thigh, ventral aspect below the inguinal glands. Twenty-one days later the animals were etherized to the point of death and smears made from the enlarged and broken down glands of the inguinal regions above the points of inoculation. Stained by the acid-fast method, these showed numerous tubercle bacilli.

Dried Agricultural Products.—An industry that is sure to be developed to a greater extent than at present, in the opinion of the *Scientific American* (June 24, 1916), is the drying of agricultural products, such as potatoes, and aqueous industrial residues, such as the products of the sugar factories and the breweries. In France, it is said, fresh beets are dried, and three beet sugar works dry the exhausted beet pulp. Another industry in France is the making of "sugar flour" from fresh beet pulp by a process using increasing temperatures up to 120 C. A flour is produced which has the sweetening property of sugar to a certain extent, which can be used in all instances when the sugar it not required to be pure, as in breweries, for special breads, for feeding stock, etc. It is said a ton of beets produces 500 pounds of flour which sells for $2 a hundred. The drying of potatoes will be of especial practical value on account of the difficulty of keeping and handling them in their raw state. Damp grain may also be dried.

BERIBERI

REPORT OF CASES *

ALFRED C. REED, M.D.
Clinical Instructor in Medicine, Leland Stanford Junior University, School of Medicine
SAN FRANCISCO

Case 1.—*History.*—K. Saito, a Japanese man, aged 44, had been in the United States for twelve years engaged in domestic work. He had not returned to Japan in that time. His family history had no medical significance. His complaints on admission to the medical clinic were headache, palpitation, digestive disturbances and insomnia. He had no history of previous acute disease and had always been in good health until five months previously, when he took cold and the present symptoms developed. Three years before he had been operated on for a fistula in ano which was cured and had not recurred. He had had no digestive disorder before the condition for which he now sought relief. His weight had not varied from 155 to 160 pounds for five years past.

Physical examination showed a middle aged Japanese, fairly well developed and nourished. His pupils were equal, medium, regular and reacted to light and accommodation. His teeth were in poor condition with much caries and pyorrhea. The gums were spongy. The pharynx and tonsils were negative. No abnormality was detected in the lungs. The heart showed some increase of transverse cardiac dulness from a half inch to the right of the right sternal border to a half inch outside the nipple line in the fifth left interspace. The impulse could be felt over the entire precordium, but there was no murmur or thrill. The area of the great vessels was not perceptibly widened to percussion. The radial pulse was equal, regular, 86 and the arteries thickened. The systolic pressure was 165 mm. (Faught).

The abdomen was symmetrical, protuberant and very tympanitic. Hepatic and splenic dulness were not increased, nor were these organs palpable. The extremities showed a deep tense pretibial edema. The knee jerks were absent and the Achilles jerk decreased. There was a sensation of numbness in the legs, but no anesthesia or muscular weakness could be detected. Some soreness was complained of over the nerve trunks of both upper and lower extremities. The patient said he had considerable numbness and tingling of the legs and a cap-sensation of numbness over the cranium. There was no motor or static ataxia. Some hyperesthetic areas were found on the sides of the chest and on the thighs. There was no disturbance of temperature sense. The nervous system findings were confirmed in the neurologic clinic.

Special examination of the eyes showed no refractive error or lesion of the fundi. There was moderate puffiness under the eyes. The patient stated that his diet consisted largely of milled or polished white rice, in fact, that it constituted the major portion of his food and had for many years. He had no venereal history and no evidence of having had venereal infection. A second examination of the eyes showed fundi and visual fields normal. Ears, throat and nose presented no abnormality. The clinical course was one of steady improvement both subjectively and objectively under a treatment of rest in hospital, where he was referred to the clinic ward for observation, mixed diet and mild tonics. He had several crops of boils which healed with no ill effects. Temperature, pulse and respiration were always within normal limits.

Laboratory Findings.—Blood: Average blood count gave 80 per cent. hemoglobin (Dare), white cells, 5,600; polymorphonuclears, 64 per cent.; lymphocytes, 26 per cent.; mononuclears, 3 per cent.; eosinophils, 5 per cent., and transitional cells 2 per cent. Stool: No occult blood. Practically normal digestion. Numerous clonorchis ova. Urine: Neutral, specific gravity 1.020, very slight trace of albumin, no sugar, a few hyaline and finely granular casts, epithelial cells and mucus. Wassermann reaction on blood serum was negative. Ten days after a provocative intravenous injection of 0.5 gm. arsenobenzol, the Wassermann reaction was still negative. Roentgenogram of the bony spine showed no abnormality.

---

* Presented before the Cooper Clinical Society, San Francisco, May 8, 1916.

Spinal fluid At the first examination, the Wassermann reaction was suggestive of positive (1, + + +, 0 5, + + +, 0 1, + + — —, 0 025, — — —) 1 polymorphonuclear cell per cubic millimeter Nonne Appelt phase 1, very slightest trace Noguchi butyric acid reaction, negative In view of these findings the patient was given 0 5 gm arsenobenzol intravenously, and ten days later the spinal puncture was repeated On second examination the Wassermann reaction was negative in all dilutions One polymorphonuclear leukocyte was found per cubic millimeter Nonne-Appelt phase 1 and the Noguchi reaction were negative The colloidal gold reaction was 0, 0, 00000000 Gastric contents Ewald test meal, removed by tube in one hour, was well digested, no blood, a little mucus, occult blood, + + Total acid, 30 Free hydrochloric acid, 12 Phenolsulphonephthalein excretion (1) First hour, 45 per cent, second hour, 40 per cent, total 85 per cent (2) First hour, 40 per cent, second hour, 20 per cent, total, 60 per cent

This case on summary presents an interesting combination of findings The diagnosis of beriberi is supported by the cardiac palpitation and enlargement, with pretibial edema, exposure to beriberic conditions an afebrile course, and a peripheral neuritis There was undoubtedly present a low grade chronic nephritis which, however, did not seem severe enough to account for the edema The high phenolsulphonephthalein excretion, moderate blood pressure, and absence of other evidence of marked renal insufficiency point rather to beriberi as the principal pathologic condition The diagnosis must include alveolar pyorrhea, cardiac hypertrophy, and arteriosclerosis of a moderate degree

The clonorchis infection would help account for the pretibial edema, as it was evidently of long enough duration and intensity to produce an eosinophilia Presumably the patient contracted the clonorchis at least twelve years before in Japan The fluke would account, too, for the digestive disturbances

As for the seriousness of the clonorchis infestation, opinion differs In sections of China in which from 12 to 20 per cent of the population are infected, the disease is rather disregarded While the fluke cannot be eradicated, it is not considered a particularly dangerous parasite Clonorchis ova have been found in the abdominal lymphatics, and the fluke inhabits the bile duct system as well as the duodenum It does without question produce various gastro-intestinal disturbances, and the question of a toxin must be considered, especially if, as in this case, the eosinophilia and in any part the edema, are to be ascribed to the parasite The further possibility of egg embolism is to be kept in mind Dr Herbert Gunn states that he has found about 14 per cent clonorchis infection in the routine examination of a large series of orientals in San Francisco Cases are not infrequent in the Stanford medical clinic

Case 2—L F S, a Chinese man, aged 42 came to the medical clinic complaining of tiredness and numbness of the legs with frequent urination and some irregularity of the bowels The condition was of gradual onset, was progressive and was first noticed five or six months previously The family history was of no medical significance except that the father had died from pulmonary tuberculosis at the age of 73 There was no history of previous illness beyond frequent colds and much headache There were no symptoms referable to the respiratory, circulatory or gastro-intestinal tracts There was no history or evidence of venereal disease

Up to the time of admission to the clinic, the patient had frequent nocturia and six or more urinations in the daytime His habits were abstemious He had been in the United States for thirteen years except for a period of sixteen months ending six months previous to admission, during which time he was visiting at his home near Canton China

The immediate illness consisted solely of numbness and weariness of the lower extremities, with headache, frequent urination, cold hands and feet, and at times constipation

Examination revealed the patient rather pallid, moderately developed, and somewhat below the average stature The teeth showed marked pyorrhea and caries The pupillary reflexes were normal The chest showed sunken supraclavicular fossae with corresponding dulness There were no rales and no change in fremitus, voice or breath sounds The cardiac dulness was not increased, and the sounds were of good quality and free from murmurs After vigorous exercise a slight irregularity was noted The radial pulse was equal, regular and of moderate tension The abdomen showed no abnormality There were marked cyanosis and some clubbing of the fingers A general adenopathy was present The patellar reflexes were greatly exaggerated At first a tentative diagnosis was made of underlying pulmonary tuberculosis with a secondary anemia The laboratory examinations showed a moderate anemia with an eosinophilia of 5 per cent Occult ova and trichocephalus ova were found in the stool The sputum had no tubercle bacilli It was thought that there might be a further helminth infection which would more adequately account for the symptoms than trichocephalus alone With this in view, thymol was administered in the fashion recommended by Stiles, and the stools were examined, but no further ova or parasites appeared, although the occult blood disappeared

At the time the thymol was administered, it was observed that there was definite but not very noticeable edema of the ankles, and especially of the pretibial regions of both legs Also there was numbness of both legs from the midthigh down Tactile sensation was unimpaired Ankle clonus, the Babinski and Kernig reactions were negative The knee jerks were constantly exaggerated No paresthesia was observed The diagnosis of beriberi was now considered The patient was referred to the neurologic clinic with a tentative diagnosis of peripheral neuritis, which was confirmed The tendon reflexes were all lively except the Achilles, which could barely be elicited The Oppenheim reflex was negative The abdominal and cremasteric reflexes were normal Sensibility to heat and cold was normal, but with some diminution of acuity from the midthigh down No definite area of anesthesia could be mapped out, and there was no disturbance of the deep reflexes Except that a watch could not be heard on contact, there was no disturbance of the cranial nerves The neuritis while not prominent, was none the less definite

In the complete absence of albuminuria and fever, and the absence of any other intestinal parasite except the trichocephalus in small numbers, it was felt that the positive features of exposure to beriberic conditions, a peripheral neuritis, a slight disturbance of the cardiac rhythm and a pretibial edema justified the diagnosis of larval beriberi It is to be noted that no other cause for the neuritis could be found, alcohol and arsenic being ruled out among the first A latent pulmonary tuberculosis could not be excluded, but if present, was certainly not active and not sufficient to account for the symptoms Neuritis in tuberculosis is usually a late symptom, and such a cause can easily be excluded here It is usually stated that eosinophilia does not occur in trichocephalus infection, but it is none the less not infrequently seen If eosinophilia in any sense represents an anaphylactic reaction to helminth infection or helminth proteins, it is hard to see why this worm out of many should be exempt

It is authoritatively stated that in beriberi the characteristic neuritic symptoms are especially displayed by the vagus and vasomotor nerves, the former being associated with the very characteristic cardiac lesions and the latter with the edema Cardiac failure is the usual termination if recovery does not take place, and it is no unusual thing to see sudden and quite unforseen acute dilatation of the heart in patients who even a few minutes before were apparently comfortable It is hard to relate the entire cardiac pathology to the vagus, and it seems more reasonable that there is some local toxic influence on the heart Before the cardiac irregularity was discovered in the case here presented, it was felt that the apparently normal heart was distinctly against the diagnosis of beriberi

FILARIASIS

REPORT OF TWO CASES IN THE DISTRICT OF COLUMBIA, AND ANALYSIS OF THE CASES REPORTED FOR EASTERN NORTH AMERICA *

MARCUS W LYON, JR, PH D, M D
WASHINGTON, D C

The term "filariasis" as here used is restricted to infections with *Filaria bancrofti* or at least with worms having embryos apparently of that type Most of these infections in the northern states have occurred in persons who have acquired the parasite in the tropics and are consequently lacking in the interest which indigenous diseases possess As an examination of the published cases, however, shows that, excepting two large series reported from Charleston, S C, less than fifty have been recorded for eastern North America, one may perhaps be pardoned for reporting two other imported cases, especially as the disease may become endemic in this latitude, if it not already is

Following a consideration of these two cases is a summary of what, it is hoped, are all of the cases previously reported, with a discussion of each case or group of cases As compilers are only human, probably recorded cases in eastern North America have been inadvertently overlooked Only cases in which adult or embryo worms were actually found have been considered

It is not to be supposed that the 142 cases reported for eastern North America represent anything like the incidence of filariasis in this country They are more apt to represent careful diagnosis and interest on the part of observers to report them Judging by the large number of indigenous cases found in Charleston, S C, one would expect them to be equally numerous in other southern cities, yet but few have been reported in them In going through the *Index Medicus,* the indexes of THE JOURNAL, the International Catalogue of Scientific Literature and the cards of the Zurich *Concilium Bibliographicum* in looking for published records, I made no special effort to search for reports of filariasis on the Pacific coast Two published records, however, show it to be present there Wellman, von Adelung and Eastman[1] report filariasis as constantly present about San Francisco Bay, and describe some experiments with feeding mosquitoes on an infected Japanese, von Adelung[2] reports a case of chyluria in a Japanese, with embryos present

As previous writers and the standard textbooks deal with the morphology, the life history, etc, of *Filaria,* and as these facts are generally well known at the present time, no reference to that aspect of filariasis will be made here Only an analysis of the cases previously described in eastern North America and the two here recorded will be attempted

REPORT OF CASES

CASE 1—Colored medical student at Howard University, in 1902, between 20 and 25 years of age, native of Trinidad, West Indies

This case was accidentally discovered by Dr Paul Bartsch in teaching histology At that time the medical course at Howard University was given at night, and in the routine study of students' fresh blood the moving embryos were found This student was well developed, as shown by anthropometric measurements taken by Dr Bartsch, and had no chyluria or enlarged glands He appeared mentally listless and was unable to complete his medical course on that account When first coming under observation he had been away from Trinidad for three years, and was under Dr Bartsch's observation for one and a half years when he left the medical school and was lost sight of Embryos were present in his blood when last seen, that is, four and a half years since leaving the tropics The largest number of embryos found in a single drop of blood was seven, or about 150 per cubic centimeter in blood obtained after 10 p m At 8 p m an occasional embryo was found in a drop, sometimes none, never more than one During the day embryos were never found in drops examined, although many attempts were made to find them At that time Rivas and Smith's method of drawing a few cubic centimeters from a vein and placing it in dilute acetic acid solution was unknown In petrolatum ringed preparation of drops of blood, Dr Bartsch has observed the embryos moving after a lapse of twenty-two days The listless condition of this patient may have been due to a simultaneous infestation with hookworms, but his feces were not examined for them I doubt if filariasis was the cause of it

CASE 2—Patient of Dr George N Overton who suspected filariasis, and in conjunction with Dr Walter Van Swearingen made a positive diagnosis by a night examination of the blood Dr Overton has kindly furnished blood from this patient for the past three years for use in my classes in clinical microscopy Living embryos from this case were exhibited[3] at the Biological Society of Washington, March 25, 1916

The patient is a bright, intelligent colored girl, aged 19 years, born in British Guiana She has lived in Panama, whence she came to Washington in 1911, five years ago, in order to attend the Armstrong High School where she was graduated this year Her family history is negative except for a sister who has filariasis (diagnosed by symptoms), now living in British Guiana Eight years ago while in British Guiana, she first noticed swelling of the right leg, later attended with intense pain and a "drawing" sensation of the limb, with headache, fever and chills, often she would retire feeling well only to be awakened with these symptoms, walking or any vigorous exercise would precipitate an attack During these attacks there appeared a large lump in the right inguinal region which would slowly travel down the thigh, then to the leg and finally disappear in the region of the ankle These attacks would number about three a month lasting about one week She received medical treatment at Demarara and Panama with negative results In 1911 she came to the United States, and was soon after attacked in usual way Three years ago she came under Dr Overton's care and the positive diagnosis of filariasis was made This patient's blood has been examined only at night, from 9 to 10 p m, and shows from one to three or four embryos in each drop, this is about 20 to 100 embryos per cubic centimeter Aside from the embryos and an eosinophilia of from 10 to 15 per cent, her blood picture is normal The treatment given by Dr Overton has been local applications of ichthyol and iodin to the inguinal region, thigh, and leg, and a course of Fowler's solution and later of Donovan's solution Under this treatment the local and systemic symptoms cleared up, but the embryos still persist in the blood Continued residence in the temperate zone and the tonic effect of the treatment tried are probably responsible for her improved condition I do not believe the treatment has had direct effect on the adult worms I found as many embryos in the blood this year as I did three years ago The contrast in mental picture between this case and the preceding listless patient of Dr Bartsch is marked

---

* Because of lack of space this article is abbreviated in THE JOURNAL A synopsis of all the cases heretofore reported in eastern North America will appear in the author's reprints A copy of the latter will be sent by the author on receipt of a stamped addressed envelope

COMMENT

The source of infection in both cases was undoubtedly the tropics The possibility of filariasis being spread from cases imported into this latitude must not be lost sight of Mr Frederick Knab of the Bureau of Entomology informs me that what is probably the important intermediate host in the spread of *Filaria bancrofti,* the mosquito known as *Culex quinquefasciatus* Say (formerly *Culex fatigans* of authors, also called *Culex pipiens* by Cuban authors and *Culex ciliaris* by Manson) is abundantly found in Washington during the late summer It seems not unlikely that the summer temperature conditions in this latitude are suited to the development of the embryos into infective forms That this actually has happened is perhaps shown by Barnes'[4] Washington case, by Slaughter's Alexandria, Va, cases and by Dunn's[6] Philadelphia case According to Mr Knab the known range of *Culex quinquefasciatus* is as far north as Washington, D C, St Louis, and San Francisco It has not been recorded in either Baltimore or Philadelphia, but Mr Knab thinks there are no climatic reasons why it might not be found in those cities

The possibility of infected mosquitoes being imported with bunches of bananas or other tropical fruits, as suggested by Johnstone[7] in reporting a possible Chicago case, and thus spreading filariasis beyond its endemic zone, should be considered Mr Knab, however, thinks this is a rather unlikely manner of carrying *Culex quinquefasciatus* On the other hand, he believes there is considerable likelihood of infected female mosquitoes traveling from the tropics in the cabins or elsewhere on ships, and thus infecting individuals outside of the endemic zone *Culex quinquefasciatus* is a house-inhabiting mosquito, and might readily be found in the rooms of vessels There seems to be no reason why they might not also travel in the coaches of passenger trains from an endemic center like Charleston to more northern cities

SUMMARY

Two imported cases of infection with *Filaria bancrofti* are reported for the District of Columbia

Including these, 142 cases have been reported in eastern North America, 7 of which are doubtful records One hundred and four acquired their infection in the United States, 28, in the West Indies or in South America, 1, in Egypt, 2, unknown but probably in the United States

Distributed by sex and race, the 135 positive cases show white males, 25, colored males, 38, males, race not stated or inferable, 12, total males, 75, white females, 21, colored females, 37, females, race not stated or inferable, 2, total females, 60, total white, 46, total colored, 75, race not stated or inferable, 14 The somewhat greater frequency of infection in males is probably associated with their seeking medical advice for involvement of the scrotum The rather marked frequency of infection in the colored over the white is probably associated with the fact that in the large Charleston series the colored patients come from a class more apt to be bitten by mosquitoes Excluding the Charleston cases the figures are white males, 11, colored males, 4, males, race unknown, 12, white females, 5, colored females, 2, females, race unknown, 2, total males, 27, total females, 9, total white, 16, colored, 6, race not stated, 14 The ages of the patients varied from 6 years to old age

Pathologically the cases show no or almost no symptoms directly referable to the parasite or suffering from other affections, 72 cases, that is, about 50 per cent, chyluria or hematochyluria, 36 cases, elephantiasis of the legs, 3, scrotal enlargement of various kinds, 13, inguinal enlargements, 11 Of the cases with chyluria, two showed that the chylous urine was passed by a single ureter, in one the right, the other, the left This may have been the case with many of the others, as probably only a few were cystoscopically examined In one case with inguinal enlargement the mistaken diagnosis of hernia was made, and in one with scrotal involvement a supposed tuberculous testicle was removed A moderate eosinophilia (from 10 to 15 per cent) was present in most of the cases, but was entirely absent in some

In those patients who became pregnant and had children, the embryos were not found in the child's blood or in the mother's milk (Henry's[22] Philadelphia case, Saussure's,[44] and Johnson's[45] Charleston cases Compare, however Barnes'[4] Washington case)

Geographically the eastern North America cases are distributed from Canada to New Orleans and Key West, and from Boston to St Louis There is a large endemic center in Charleston, and probably elsewhere in the South Indigenous cases are found along the Atlantic seaboard as far north as Philadelphia, but most cases north of Charleston are imported ones

Culex quinquefasciatus, the mosquito which serves as the intermediate host for *Filaria bancrofti,* ranges as far north as Washington and St Louis and perhaps farther It is a house and city mosquito

Adult worms remain living in their human host and give forth embryos for at least five years (Brooklyn and Washington cases), and probably thirteen years (Rosenberger's Philadelphia case)

The diagnosis is easily made by examining for living embryos in drops of fresh blood obtained at night, or by the Rivas-Smith method of placing a cubic centimeter of blood, day or night, in dilute acetic acid solution and examining the centrifuged sediment The number of embryos found varies from one to over 2 000 per cubic centimeter, depending on the time of day or night examined and probably the number of parent worms

Surgical interference, where the parent worms are accessible, has usually been successful when employed

Medicinal treatment is unsatisfactory In some of the foregoing cases salvarsan has apparently given good results Branch[48] speaks highly of it in the West Indies Cottle,[49] in the Pacific, thinks it ineffective

DISTURBANCES OF THE KIDNEYS

(Continued from page 35)

ALBUMINURIA IN INSURANCE

A broader point of view and better knowledge of functional or accidental albuminuria have made its discovery in applicants for insurance a cause for reexamination of the urine, and not a cause per se for rejection. That albuminuria is not normal is acknowledged, and when it is found more than once in an applicant he is either rejected or his acceptance postponed. The age of the person in whom it is found is of importance, as after 40 even traces of albumin are suspicious. For the same reason an occasional hyaline cast may not be alarming in persons under 30, in those over 40 it is ominous. An applicant in whom albumin is found should be reexamined unless the amount is considerable. After four negative specimens and an absence of casts, with a blood pressure below 140 mm. systolic, or with a diastolic below 100 mm. if the systolic is 150, with cardiac sufficiency, and with no history of syphilis, tuberculosis or any renal disease, the applicant should be accepted. Any signs of cardiac hypertrophy or symptoms of hypertension should cause the applicant to be rejected.

A specific gravity of anything less than the whole twenty-four hours' urine is unimportant. A single specimen may vary from 1.005 (nervous urine, or urine passed soon after a long summer drink, or in severe cold weather) to 1.025, and still not indicate the average specific gravity. A high specific gravity, namely, more than 1.025, without sugar and without normal sediment, is rarely found in applicants for insurance. An abnormally low specific gravity of the urine is frequent, and in such cases most insurance companies require another examination; such an examination, however, is not justified on these data alone.

As the action of tobacco on the heart, blood vessels and kidneys is positive, a question of great importance, which the applicant should answer, is, "How many cigars, cigarets, and pipes do you smoke a day?" This is not yet often asked on insurance examinations, but is just as important today (there being fewer men who drink to excess) as is the question, "How many glasses of beer or whisky do you drink a day?" It is not sufficient to determine that the blood pressure is not too high in those who smoke to excess, as the high blood pressure may have become normal as a result of the weakening of the heart muscle by tobacco.

Occasionally a peculiar nervous albuminuria occurs in certain persons while under some nervous tension. However, although this condition often accompanies such nervous tension, these people never give evidence of orthostatic albuminuria. It is, of course, possible that at times some associated but undiscovered cause is present.

There are also instances of albuminuria in active persons with casts in the urine for years without any apparent progression, whose death will not be due to cardiovascular-renal disease. In such cases data of kidney function tests and of the nonprotein nitrogen of the blood should be obtained. We can no longer assume that hyaline or a few granular casts demonstrate nephritis. They do demonstrate some abnormal congestion or disturbance in some part of the kidney, but such a disturbance may completely disappear, as can a mild disturbance in any other part or organ of the body. On the other hand, coarse granular, fatty and waxy casts show kidney inflammation.

Traces of albumin may result from inflammation of the prostate and of the seminal vessels, and, of course, from pus anywhere in the urinary tract. In albuminuria from vesiculitis, Belfield[58] finds that if the urine is passed into three glasses, a little into the first, the bulk into the second, and a little into the third, a good reaction is found for albumin in the first and last glasses, but less in the second glass, while in renal albuminuria all of the urine tests the same. In prostatitis, massage of the prostate will increase the albumin in the urine passed immediately afterward. This is especially significant if the bladder has been previously washed. Of course urine drawn by ureteral catheters will positively prove the source of the albumin.

(To be continued)

THE MODERN TREATMENT OF MERCURIAL POISONING

Cases of mercurial poisoning, particularly with mercuric chlorid, are so common nowadays that we should be ready to treat these patients promptly. It is equally essential that every hospital should be prepared to treat patients with mercuric chlorid poisoning properly as soon as they are received. Until quite recently the prognosis was far from favorable, but the considerable degree of success attained of late in the management of mercury intoxication has given new hope and encouragement for vigorous attention in every case.

The excellent suggestions of Lieb and Goodwin[1] and of Lambert and Patterson[2] on which the prevalent mode of treatment is based have lately been supplemented by the further studies of Lewis and Rivers[3] at the Johns Hopkins Hospital. The keynote in the procedure is elimination, which must be encouraged energetically by every available method. The Baltimore investigators point out that many apparently moribund persons have been saved by properly directed and vigorously pushed therapeutic measures. Death should be the only indication, they remark, for a discontinuance of treatment prior to the complete recovery of the patient.

Inasmuch as the excretion of mercury into the stomach and intestine as well as its appearance in the sweat has been definitely demonstrated by chemical investigations, the instructions to wash out the stomach frequently, to irrigate the colon liberally and to induce perspiration by means of a hot pack are placed on a rational basis. The administration of alkalies is based on the work of Macnider, who, in an article in the *Journal of Experimental Medicine* (1916, 23, 171), shows that they are capable of protecting the kidney from the full renal effect of salts of heavy metals like uranium which lead to pronounced nephritic disease as mercury does. Sodium bicarbonate exerts a diuretic action in addition, and there are indications of a decided benefit when it has been employed in mercury poisoning.

[3] Lewis, D. S., and Rivers, T. M.: Chemical Studies on a Case of Bichloride Poisoning, Bull. Johns Hopkins Hosp., 1916, 27, 193.

The high figures reported for nonprotein nitrogen of the blood indicate the retention of nitrogenous waste, which is undoubtedly a factor in the early fatal issue of some cases Lewis and Rivers,[3] therefore, urge the administration of carbohydrate in the form of glucose, either by mouth or intravenously, in a 10 to 50 per cent solution In addition to serving as a mild diuretic, it is believed to exert a protein-sparing action and thereby delay the appearance of extreme grades of nitrogen retention which usually precede death

As an index to the changes in the renal function the specific gravity curve of the urine should be studied in addition to the familiar functional tests for kidney performance Mosenthal[4] has shown how much information may be gained regarding the condition of kidney function from a study of this factor In nephritis, marked fixation of the specific gravity at a low level occurs in only the severest types This is characteristic of a kidney which has no reserve power whatever and is therefore compelled to function constantly at its maximum capacity in order to eliminate the end-products of metabolism which ordinarily find an exit from the body in the urine The variations in the concentration of the urine, as expressed by its specific gravity, become more and more conspicuous as renal function approaches normal

The accumulation of reliable guides based on careful studies of mercury poisoning are a fortunate accession to modern therapy Any treatment which has a rational background of scientific indications to support it is always undertaken with greater zest, confidence and persistence than are the haphazard makeshifts of empiric rules The indifference bred of failure is no longer justified Quoting Janeway[5] in respect to the management of cases of mercuric chlorid poisoning, every practitioner either should know how to treat these patients, or should get them promptly to the nearest hospital that does

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION W A PUCKNER, SECRETARY

UREASE

Urease is a urealytic enzyme found in certain beans fungi and micro-organisms

Actions and Uses—In the presence of water, urease converts urea into ammonium carbonate, thus $(NH_2)_2CO + 2H_2O = (NH_4)_2CO_3$ It is employed in the determination of the amount of urea in the urine, blood and other body fluids

Dosage—For the estimation of urea in the urine, two methods are used with various modifications 1 A measured amount of urine is treated with urease, and after a specified time the ammonia produced is drawn into volumetric acid by means of an air current, and the residual acid determined by titration ("Absolute Method" D D Van Slyke *Jour Biol Chem*, 1913-1914 **16,** 125) 2 The alkalinity of a portion of urine, treated with urease, is determined with volumetric hydrochloric acid (methyl orange being used as an indicator) This figure is corrected for the acidity or alkalinity of an equal volume of the same urine determined with the same reagents The corrected figure represents the ammonium carbonate formed by the conversion of the urea present (Marshall, *Jour Biol Chem*, 1913, **14,** 283)

The amount of urea in blood is determined by treating as in Method 1, the blood having been mixed with potassium citrate, to prevent clotting as soon as drawn

UREASE-SQUIBB—Jack bean urease—A standardized preparation of the urealytic enzyme obtained from the jack bean, *Canavalia ensiformis*

Actions Uses and Dosage—See general article on urease above Urease-Squibb is supplied in the form of powder and tablets

Manufactured by E R Squibb and Sons, New York No U S patent or trademark

Urease Squibb Tablets 0 1 Gm—Each tablet contains 0 1 Gm urease Squibb

An aqueous extract of the jack bean is filtered the clear filtrate reduced to dryness the dry powder extracted with absolute alcohol, acetone and ether dried, and the dry powder mixed with monopotassium phosphate and dipotassium phosphate in proportion to produce the maximum hydrolytic action and stability of the enzyme

It is a fine white, practically odorless and tasteless powder which dissolves readily in cold water, forming an almost clear solution

If 0 1 Gm of Urease Squibb in 1 Cc of water be added to 5 Cc of phosphate urea mixture (according to the absolute method') and digested at 20 C for fifteen minutes, it will decompose sufficient urea to liberate from 100 to 150 Cc of fiftieth normal ammonia by aeration

NEUTRAL SOLUTION OF CHLORINATED SODA—Solution Chlorinated Soda, Dakin—Solution Chlorinated Soda, Carrel-Dakin—A chlorinated soda solution, containing 0 43 to 0 48 per cent of available chlorine, free from caustic alkali It must be protected from light

Actions and Uses—Neutral chlorinated soda solution has the germicidal and other properties of solution of chlorinated soda U S P but because of its freedom from alkali is not irritating to the tissues It does not coagulate or precipitate the proteins of the lymph exudate in wounds, nor does it inhibit leukocytosis or phagocytosis or the digestive action of tryptic enzymes It has been used after the first cleansing and in the subsequent more or less continuous irrigation of wounds, especially of infected war wounds Whether its action in this case is to be attributed to the real antiseptic or germicidal effect is still doubtful

Dosage—For external use full strength

Place 154 Gm chlorinated lime assaying 30 per cent available chlorine (by the method of the U S P) and 5 liters of water in a jar, stir thoroughly and let stand for 6 to 12 hours Add to this with constant stirring a solution of 91 Gm monohydrated sodium carbonate and 64 Gm sodium bicarbonate in 5 liters of cold water After one half hour siphon off the clear liquid and filter it through double filter paper to obtain a clear solution Transfer the liquid to glass containers and keep dark (If the chlorinated lime contains a larger or smaller amount of available chlorine than 30 per cent each of the ingredients to be used in making ten liters should be proportionately decreased or increased)

If to 20 Cc neutral solution chlorinated soda about 0 020 Gm phenolphthalein in powder is added no red color develops on agitation

If the available chlorine of neutral solution of chlorinated soda is determined by the U S P assay method for *liquor sodae chlorinatae* it should contain not less than 0 43 per cent nor more than 0 48 per cent available chlorine, equivalent to not less than 0 45 per cent nor more than 0 50 per cent sodium hypochlorite (NaOCl)

THEOBROMINE (See New and Nonofficial Remedies, 1916, p 376)

Theobromine-Merck—A nonproprietary brand complying with the standards for theobromine

Manufactured by L Merck, Darmstadt Germany (Merck and Company New York)

BARIUM SULPHATE FOR ROENTGEN-RAY WORK (See THE JOURNAL, Oct 7, 1916, p 1091)

Barium Sulphate, P W R for X-Ray Diagnosis—A nonproprietary brand complying with the standards for barium sulphate for Roentgen-ray work

Manufactured by Powers Weightman Rosengarten Co Philadelphia

Barium Sulphate, Merck for X-Ray Diagnosis—A nonproprietary brand complying with the standards for barium sulphate for Roentgen ray work

Manufactured by E Merck Darmstadt Germany (Merck and Company New York)

PHYSIOLOGIC ASPECTS OF THE WORKING DAY PROBLEM

The length of the working day has a preeminently physiologic bearing, and recently has assumed increased political prominence Lee[1] has presented the crux of the matter as follows The eight-hour problem is primarily a problem of physiology, if the physiologic effects of any kind of labor are injurious, the conditions of such labor should be changed This is fundamental, and should precede any consideration of the economic and social effects resulting from a change of conditions, a basic fact which is continually overlooked

The most serious physiologic interference accompanying prolonged uninterrupted work is the familiar phenomenon of fatigue Its existence is generally recognized, yet few except those who have attempted a more intimate analysis of work in relation to weariness realize the subtle ways in which fatigue not only damages the working human mechanism but also tends to lower the efficiency of its performance Nowadays every student of medicine has opportunity to learn from his experimental study of physiology that the introduction of periods of rest during a laboratory experiment with a muscle diminishes the fatigue of the moment, aids recuperation, and delays the oncoming of exhaustion This fact is demonstrated in each of us several times in a minute, since each beat of the heart is followed by a period of rest to enable the cardiac muscle to recuperate from the effects of the previous contraction The beneficial effects of similar periods of rest in industrial labor, as Lee reminds us, are evidenced by the custom — not uncommon since the striking demonstration of the late Mr Frederick Taylor in the lifting of heavy iron pigs — of giving workers occasional brief intervals of freedom from their tasks

Any working day which, through conditions of intensity and rate of labor and environmental features, tends to cause the detrimental effects of fatigue should be modified Here is a large field for the careful study of conditions relating to the hygiene of work Formerly economic arguments were commonly employed to combat all attempts to reduce working hours for those performing heavy labor Recently there has been a growing conviction that in many industries a shorter working period under more favorable physiologic conditions will frequently result in an output as large as that achieved on a longer working day basis, if not even larger The question, however, is one not only of a shorter day, but also of more frequent periods of rest which may tend to eliminate the incipient fatigue which curtails efficiency

Whether or not the reduction of the working period to the eight hour day is a physiologic necessity cannot be decided on any *a priori* grounds Lee points out that two factors are to be considered the characteristics of the labor, and the capacity of the laborer Different occupations vary greatly in their fatiguing power Especially productive of fatigue are those characterized by great muscular effort, unusual quickness or complexity of muscular action, single acts, however simple, which are monotonously repeated over long intervals of time, constant strain through concentration of attention or through a bodily posture long maintained, and those occupations in which the work is carried on in crowded places, in extreme heat and humidity, in the midst of excessive noise, or under other unfavorable environmental conditions Perhaps the ideal will hinge on the establishment of a system of labor in which the length of the working day shall vary for each person according to his personal capacity

It would be folly to say that other aspects of the problem deserve no consideration in the discussion of the working day Labor leaders insist on the propriety of certain demands from the standpoint of social justice an opportunity for something more than machine efficiency, and more time for personal enjoyment and social betterment If the ideal conditions of work demanded are afforded, a serious obligation to do his best will rest on the laborer as well as on each one of us

THE SANITARY ASPECTS OF THE PUBLIC FOOD MARKET

The widespread agitation regarding the high cost of food has focused attention on various possible palliative factors, among them the public or municipal markets From the standpoint of the food economist these are assumed to contribute to better living conditions by lowering the cost of distribution, as well as by effecting other economies The food market, whether under public or private control, introduces many problems of sanitary and hygienic importance, such as the care of easily deteriorated foods publicly offered for sale, which have already been brought within the jurisdiction of municipal boards of health or other forms of inspection service

Other features are either too utopian or too difficult of enforcement to receive authoritative consideration at the present time Among these belong such matters as the personal cleanliness of food handlers and the perhaps still visionary schemes for indicating food values in some intellectually tangible manner Now that the establishment of public markets is everywhere under discussion more widely than it has been before, it may not be amiss to inquire wherein sanitary science and hygiene might play some part in the plans for the future

There are, first of all, possibilities of danger to health in the foods offered for sale They may deteriorate from natural decay, they may be adulterated by harmful additions or equally unjustified subtractions, they may become sources of infection through personal contamination or careless handling, and be responsible for the transmission of disease Such eventualities are recognized Chemical and bacteriologic laboratories should cooperate with official inspectors, as they already do in many places, to enforce rational sanitary codes Armstrong[1] believes that even greater safeguarding in the direction of standard analysis of food is likely to come in the future This has long been urged by Lusk[2] Thus he says

> The poor, 50 to 60 per cent of whose income is spent for food, waste their money in the purchase of beautiful labels or relatively expensive and unnutritious foods A publisher employing several thousand individuals says that his employees buy from choice the products advertised in his magazines Children of the poor are sent to buy food for the family and the whole expenditure of half the family's income is effected in an atmosphere of unfathomable ignorance Yet if one seeks to help, one is informed that one must not meddle with the appetites, and the funny man of the newspaper makes a witticism on the subject of "highbrow" information

In somewhat the same spirit Armstrong contends that eventually governmental authority will have to take the responsibility for food standardization, and if this standardization is to be on a rational basis, calorific values will have to be employed Further, if the purchaser is ever to be educated to the point at which she can buy her food supply on an intelligent food value basis, there will have to be a mechanism for routine calorific food analyses In the present state of development, an equipment of this kind cannot, of course, be considered a prerequisite to the market establishment At the same time, its need should be emphasized, so that in the future it may become an essential part of the municipal market control Again, it must be made clear that this is, of course, of hygienic rather than of sanitary importance Incidentally it may be pointed out that in "standardizing" foods for human consumption we should merely be imitating what has long been an enforced and now highly appreciated regulation in respect to cattle feeds

The ideal food market needs healthy employees Good food deserves to be handled by persons free from communicable disease, otherwise wherein are the advantages of the legal protection of food, offered for sale, from dust, dirt, flies and other contaminations? Much of such regulation now becoming more popular in large municipalities is confessedly in the interest of decency rather than strict hygiene With all these safeguards, however, the sanest sanitary regulations will not accomplish their best possibilities until the purchasing public is educated up to the significance of the modern, perhaps sometimes overdone, hygienic propaganda Perhaps the highest standard has rarely been presented with broader vision than by Armstrong when he said

> If eventually municipalities would meet the responsibility of having this program of personal food hygiene include, not only the infection-preventive and disease-suppressive factors of food protection but also the positive health-creative educational factors of dietary food selection, the markets would then be utilized to something like their full potentiality as creative, social forces

THE RESPONSE OF THE PYLORIC MECHANISM

The conditions which determine the gastric discharge through the pylorus into the duodenum, and the relations of gastric acidity to motility, discharge and duodenal regurgitation have a direct bearing on the diagnosis and treatment of disorders of the stomach Recently the application of the Roentgen ray to the examination of movements of the alimentary tract in its various sections has led to definite conclusions as to the normal performance of the pyloric mechanism Thus it is reported, as the result of observations on experimental animals, that if the secretion of gastric juice is deficient the opening of the pylorus is not easily accomplished The opening of the pylorus, however, seems to depend not only on intragastric events but also on the condition of the duodenum So long as the contents of the latter are acid, the pylorus remains firmly closed For example, it has been reported that if alkaline fluid is introduced into the stomach, it is passed rapidly into the duodenum, but if acid is introduced simultaneously by experimental devices within the duodenal canal, the pylorus remains shut and no fluid passes beyond its portals until the acid which bathes the duodenum is neutralized by alkaline juices secreted into the gastrointestinal lumen

Starling[1] summarized the subject by saying that we probably have in the walls of the alimentary canal a local nervous mechanism for the movements of the pyloric sphincter This may be played on by impulses starting either in the stomach or in the duodenum, probably by the contact of acid with the mucous membrane Increasing acidity on the side of the stomach causes relaxation of the orifice, whereas acidity on the duodenal side causes contraction of the pyloric orifice The exact parts, however, played in the mechanism by the local system and by the central nervous system, respectively, have not yet been thoroughly made out, though there is no doubt that these movements may proceed independently of any connection with the central nervous system

[2] Gephart F C and Lusk, Graham Analysis and Cost of Ready to Serve Foods, Chicago American Medical Association 1915 p 15

[1] Starling E H Human Physiology, 1915 p 700

It has lately been pointed out that these deductions, drawn largely from observations on laboratory animals, are not entirely in accord with clinical observations It is asserted that in cases of so-called hyperacidity, a retarded emptying of the stomach with resulting atony and dilatation is often found, and also, that in cases of achylia gastrica, in which there is practically no free acid found in the stomach, the normal rate of discharge is often unimpaired It seems probable, therefore, that the presence of an acid reaction is not the only essential factor in the control of gastric discharge It would be futile to recite the details of the conflicting reports Further carefully planned investigations in this field are clearly needed to unravel the tangle of discrepancies In recent studies by Morse,[2] of the laboratory of physiology of the Northwestern University Medical School, the abolition of sympathetic reflexes which might inhibit the effects sought to be determined was accomplished by making observations on animals in which the spinal cord was in part destroyed Quite unexpectedly throughout these experiments the presence of acid in the stomach in general has been observed to retard rather than hasten gastric discharge It is reported that water is discharged from the fasting stomach of anesthetized pithed dogs more rapidly than any percentage of acid The rate of discharge is decreased with increase of acidity Duodenal regurgitation, as evidenced by increase in the contents of the stomach often occurred at 0 2 per cent acidity, and in nearly all trials occurred at or before 0 3 per cent acidity was reached Increase in acidity increased the frequency and amount of regurgitation from the duodenum

If any more universal application may be ascribed to the experiments of Morse, it appears that the acidity of fluid gastric contents has no supreme function in producing or hastening gastric discharge, but the discharge seems to be controlled by the irritability or nonirritability of gastric contents to the duodenal mucosa This suggestion of a progressive diminution in the rapidity of discharge through the pylorus with increase in the acidity of the gastric contents is so contrary to the accepted version of what occurs[3] that at best we may speak of an old problem presented anew for solution For the moment the center of interest in the control of the pyloric sphincter has been shifted more prominently to the region of the duodenum

HEMATOPORPHYRIN

Hematoporphyrin is the term applied to one or more iron-free pigments obtained by the decomposition of color-bearing components of the blood pigment hemoglobin Its significance in medicine has been derived from the fact that hematoporphyrin is at times found as a noteworthy constituent of the urine, having a diagnostic import as a symptom of poisoning with sulphonal trional, tetronal, quinin and other drugs It has also been found in the urine in a variety of diseases which have no obvious common relationship in respect to the origin of the excreted pigment It is even stated that traces of hematoporphyrin regularly occur in the urine of healthy persons

To account for the elimination of hematoporphyrin in the urine, it is necessary to consider its antecedent possible origin from blood pigment in the body Nothing definite relating to the mode of formation or the seat of production is known at present The chemical relationships of hematoporphyrin offer a starting point for hypotheses respecting its introduction and physiologic significance It is closely related to the bile pigment bilirubin and to the urinary pigment urobilin

It is readily conceivable, therefore, that hematoporphyrin represents a stage in the destructive metabolism of hematin, the chromogenic part of the hemoglobin molecule, and that ordinarily the conversion proceeds to the stage of the bile pigment without betraying the intermediate product here under discussion If this were true, urinary hematoporphyrin as well as hematin might represent degradation products which for some reason have escaped further change and consequently are excreted in the transitory stage

Hoagland,[1] of the biochemical division of the Bureau of Animal Industry, has suggested a possible source of hematoporphyrin within the body not realized till now In a series of experiments on the aseptic autolysis of ox muscle, he observed the appearance of pigment spectroscopically identical with hematoporphyrin This result was obtained only when the air was excluded, and led the observer to conclude that the striated muscular tissue contains enzymes which, under anaerobic conditions, readily reduce oxyhemoglobin to hematoporphyrin These findings appear to Hoagland to offer a satisfactory explanation as to the method and source of production of hematoporphyrin in the body

In view of the fact that hematoporphyrinuria often is an accompaniment of cases of poisoning or disease in which the liver cells are believed to be destroyed or inactivated, Hoagland ventures a step further in postulating, on the basis of the foregoing, that probably hematoporphyrin may be a regular intermediate product in the transformation of hemoglobin into bile pigments The generally accepted view, he says, concerning the disposal of the free hemoglobin in the blood stream under normal conditions, is that the hemoglobin is converted directly into bile pigments by the liver. Such being the case, it would seem that when an abnormal quantity of hemoglobin is liberated into the blood stream, or when the activity of the liver is greatly decreased by disease or other causes, hemoglobin rather than hematoporphyrin would be excreted in the urine. Yet hemoglobin is not so commonly found under such conditions.

[3] Cannon W R The Mechanical Factors of Digestion New York 1911

[1] Hoagland R Formation of Hematoporphyrin in Ox Muscle During Autolysis Jour Agricultural Research 1916 **7,** 41

There is, however, still another circumstance which deserves mention. If hematoporphyrin is formed as readily in muscular tissue as Hoagland would lead us to believe, may we not take into consideration the further possibility that hematoporphyrin is ingested in meat products more frequently than is suspected, and that an exogenous source of urinary hematoporphyrin is thus furnished? Until more is known of the fate of this interesting blood pigment derivative in the alimentary tract, in the blood stream and in the liver, only the vaguest hypotheses can prevail as to its true significance.

In any event, hematoporphyrin is only one of a series of closely related compounds, the porphyrins, which promise to have a greater significance in physiology and pathology than has generally been accorded to them.[2] Both the porphyrins of animal origin and the chlorophyl derivative, phylloporphyrin, seem to act as photosensitizing agents, rendering the body peculiarly susceptible to noxious effects from light. Animals injected with various porphyrins promptly exhibit untoward symptoms when exposed to light, but not when kept in the dark. There are affections of the skin, as hydroa aestivale, associated with exposure to bright sunlight, in which cutaneous symptoms manifest themselves simultaneously with the appearance of hematoporphyrin in the urine.[3] In other instances, likewise attended with hematoporphyrinuria, necroses have been observed in parts of the body exposed to light.[4] Such experiences seem to be more than chance analogies.

Reflex Epilepsy from Contusion of the Kidney

O. Uffreduzzi has recently reported a case of epileptic seizures which came on for the first time after contusion of one kidney. The patient apparently had been healthy before with nothing to indicate a predisposition to nervous trouble. The convulsions were at first localized, but gradually became general, with loss of consciousness. The removal of the peripheral focus, the displaced and cystic kidney, was followed by a complete cure of the reflex epilepsy. Even if this had failed to cure the assumption of reflex epilepsy was unmistakably correct, various other factors might have cooperated in the irritation entailing the seizures. Cicatricial changes or other central or peripheral cause might keep up a tendency to epileptic seizures even after removal of the primary cause. The foregoing is from an abstract in *Pathologica*, 1916, **7**, 265.

Current Comment

METAL MINE ACCIDENTS DURING 1915

While the number of men killed in the metal mines of the United States in 1915 was less than in 1914, the fatality rate was slightly higher. In 1915, there were among 152,118 men employed, 553 men killed, a rate of 3.64 a thousand, while in 1914, out of 158,115 men employed, there were 559 fatal accidents, a rate of 3.54 a thousand. Among the 202,000 men employed in metal mines and in metallurgical plants, there were in 1915, 35,295 nonfatal injuries, 35 of which resulted in permanent total disability, 574 in permanent partial disability, 7,242 involved a loss of more than fourteen days' time and 27,144 were responsible for a loss of from one to fourteen days. The rate of nonfatal injuries was 232 a thousand, as compared with 191 for 1914. This increase in the injury rate is attributed by the Bureau of Mines, not to an actual increase in the number of accidents, but rather to the fact that better and more complete reports are secured each year. The occurrence of over 35,000 disabling injuries in one year among 200,000 employees, nearly 8,000 of which resulted in a loss of more than two weeks' time, is significant and interesting, in view of the present widespread discussion of social insurance. Eight thousand accidents with a minimum of two weeks' incapacity would amount to 16,000 weeks or 96,000 working days lost. When to this is added the loss from 27,144 minor injuries with an average loss of seven days each, amounting to 190,000 days, we have a total loss from nonfatal injuries of 286,000 working days a year in this industry alone.

NEW FACTS ABOUT PHOSPHATIDS

The phosphatids or phospholipins are the fatty substances which yield, on decomposition, phosphoric acid and fatty acids along with certain nitrogenous bases. Lecithin is the most familiar substance of this group of lipoids; another member, kephalin, has lately come into greater prominence than it has heretofore held as the result of its probable relation to the coagulation of the blood. Ever since Hoppe-Seyler pointed out that lecithin-like substances are probably present in all living cells, more or less attention has been focused on this group of compounds. It is fifty years since Diaconow[1] suggested the probable chemical structure of the lecithin of egg yolk, yet the exact structural make-up of this compound is not completely solved today. Despite this, the phosphatids have played a prominent part in a variety of physiologic speculations in respect to vital phenomena. Their physical texture and tendency to form emulsion-like solutions have given them significance in the physical phenomena of protoplasm. They are doubtless concerned in some of the reactions of immunity, such as the Wassermann test for syphilis and other changes involving the process of hemolysis. They may unite with toxins and enzymes so as to facilitate or retard biochemical reactions. Thus the phosphatids have attained a sort of scientific "popularity" far beyond the apparent deserts of their as yet ill defined chemical structure, so that new information regarding them is much to be desired Not long ago we called attention to the final demonstration that at least two phosphatids are present in milk,[2] thus answering a long debated question as to whether or not these lipoids are actually represented in this important food Osborne and Wakeman,[3] to whom this information is due, have now furnished proof that all of the phosphatids present in cow's milk are associated in some way with protein It is not unlikely that such combinations, which have long been known in the so-called "lecithalbumin" of the egg yolk, represent the form in which the phosphatids primarily exist in the living protoplasm Indeed, there is reason to believe that the proteins of the blood are engaged in similar combinations

SECRECY, THE FUNDAMENTAL

The Proprietary Association is the "patent medicine" organization of the United States, and its devious methods have been referred to many times Samuel Hopkins Adams in the "Great American Fraud" series turned the light on the activities of the concern in a general way, while Mark Sullivan in "The Patent Medicine Conspiracy Against the Freedom of the Press' gave specific instances of its tricky methods The Proprietary Association used to publish annual reports giving a list of its members and representatives, as well as of its associate members and the names of the concerns these members represented Apparently, it no longer does so and the membership of the Proprietary Association seems to be a close secret After each annual meeting the drug journals usually publish the list of newly elected officers, and that is about the extent to which the public is given any hint as to who comprise this "patent medicine" organization The Proprietary Association has claimed to be doing some house-cleaning — Heaven knows it is needed! — within its own ranks As there is no possible way of checking up on the question, it is a safe claim to make If a "patent medicine" faker is "caught with the goods" the Proprietary Association can conveniently disown any connection with the guilty party It is a fitting commentary on much of the "patent medicine" business that the organization which represents it should be so ashamed of its own membership that it is unwilling to make it public Secrecy in composition! This is the watchword of the 'patent medicine" industry, not only as it applies to its products, but also as it applies to its official organization!

A Sad Commentary—It is a strange commentary on man that his greatest gifts for good are so grossly neglected The church's flagging interests must be kept alive by quasi-secular amusements, angel cake and church suppers—while the tuberculosis campaign subsists on the Red Cross stamp and the small change which seductive, begging letters may withdraw from a reinforced pocket—*Bull*, Newark (N J) Dept of Health

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest such as relate to society activities, new hospitals, education public health, etc)

ALABAMA

Personal—Dr Francis E Harrington, U S P H S, has been granted a leave of absence by Surgeon General Blue to take charge of the health work of Jefferson County Dr Harrington was elected full time health officer of Jefferson County

Health System Needed in Birmingham—The Jefferson County Medical Society adopted resolutions at its December meeting, calling on the various woman's clubs, commercial organizations and citizens to appear before the board of revenue to urge a large appropriation for the installation of a unified health system, recommended by Surg Carroll Fox, U S P H S

New Officers for Mobile Society—At the annual meeting of the Mobile County Medical Society, December 2, the following officers were elected president, Dr James J Peterson, vice president Dr Lee W Roe, secretary, Dr Willis W Scales (reelected), and treasurer, Dr Eugene Thames The society also recommended Dr Paul J M Acker as county health officer, Dr Eugene Thames as physician to the County Jail and Poor Asylum, Dr Edward C Terrill as physician to the Pine Grove Hospital, and reelected Dr M Toulmin Gaines as a member of the Committee on Public Health and Board of Censors

ARKANSAS

License Revoked—Official notice from the State Medical Board of Arkansas says that at its meeting held Dec 28, 1916 the license of Dr W C Baldwin, Helena was revoked for claiming through public advertising a special ability to treat and cure chronic and incurable diseases

Hospital Notes—The superintendent of the Sebastian County Hospital announces that accommodations for twenty-five additional patients are now ready The third floor of the building has been remodeled, so that it has five five-room wards, an operating room and sterilizing room

State Health Board Appointments—December 30, Governor Hayes reappointed Drs Burrell A Fletcher, Augusta, and Henry L Montgomery, Gravelly, as members of the state board of health, and also named Dr Fergus O Mahony, Eldorado, to succeed Dr Andrew L Buckner, Dermott, on the board

COLORADO

Barker in Denver—Dr Lewellys F Barker of Johns Hopkins University delivered an address on 'Internal Secretions" before the Medical Society of the City and County of Denver, December 26

Personal—Dr George B Packard Jr, who for the last six months has been a surgeon in the allied service on the western war front sailed for home, December 16——Dr Charles A Powers, Denver, after a short vacation has returned to his work in an American hospital in Paris

Public Health Administration—In *Public Health Reports*, Dec 29, 1916, appear the results of a study by Surg Carroll Fox, U S P H S, of public health organization and administration in Colorado, similar to the studies made under the direction of the Public Health Service in other states Among the recommendations made for the improvement of the health service in the state are the creation of full time instead of part time positions of secretary, medical inspector, sanitary engineer, bacteriologist and some others, the increasing of their salaries, the establishment of a well equipped laboratory, energetic efforts to secure notification of reportable diseases, and complete birth and death registration Laws requiring this are now on the statute books A reorganization of the board on a different plan is recommended, as well as increased appropriations

DISTRICT OF COLUMBIA

Medical Examination of Schoolteachers Made Compulsory—The board of education has promulgated rules requiring teachers in the public schools to undergo medical examinations to determine their physical fitness whenever the supervising officer immediately responsible for their work so directs The rules are intended primarily to provide against the continuance in school of teachers suspected of suffering from communicable diseases or of harboring infection endangering the health of their pupils

ILLINOIS

Chicago

Clemenson's Sentence Commuted—The sentence of imprisonment for life imposed on Dr Haldane Clemenson eight years ago for the murder of his wife was commuted December 26, to twenty-five years by order of Governor Dunne With the good conduct allowance, this will allow Dr Clemenson to be released in 1923

Polish Physicians Elect Officers—At the annual meeting of the Chicago Polish Medical Society the following officers were elected president, Dr Wladyslaw A Kuflewski, vice president Dr Anthony Balcerzak, secretary, Dr A Pietrzykowski (reelected), and treasurer and editor in chief of the *Polish Medical Bulletin* Dr Nicholas Kalinowski (reelected)

To Combat Paralysis—The health commissioner of Chicago has sent to the finance committee of the council a request for $500,000 to combat infantile paralysis during the coming year in addition to the regular budget of the health department The commissioner urges that no decrease be made in the working force or the appropriations for the health department, notwithstanding the financial condition of the city

Contagious Disease Hospital Opened—The new Municipal Contagious Disease Hospital was opened, January 7, when fourteen scarlet fever patients were admitted The building is five stories in height. Four floors will be devoted at present, to scarlet fever patients At a meeting of the Chicago Medical Society, January 3 a resolution was adopted endorsing the recommendation that the hospital be called the Alfred C Cotton Hospital

Personal—Dr Edward K Armstrong was selected as superintendent of the new Contagious Disease Hospital by a committee consisting of Drs A. J Ochsner, D A K Steele A Augustus O Neil and J V Fowler He accepted the position and took charge of the institution, January 4——Dr William Healy, director of the Juvenile Psychopathic Institute, has resigned to take charge of the Judge Harvey Baker Foundation, a similar institution in Boston——Dr John Webster Melody resumed his series of lectures on Moral Law in the Medical Profession" January 7 at St Jarlath's Hall, Hermitage Avenue and Jackson Boulevard——Dr Charles F Swan, for many years a practitioner of South Chicago and who has been visiting in Vancouver Wash since last September was stricken with cerebral hemorrhage, December 24——Dr Abraham L Desser was seriously injured in a collision between his automobile and a street car, December 31

INDIANA

State Health Officer Gives Luncheon—Dr John N Hurty, secretary of the state board of health gave his annual Christmas luncheon to the employees of the board, December 22

Leprosy in Indianapolis—A case of leprosy was reported December 11, from the Robert W Long Hospital Indianapolis the patient being a man 69 years old from Fort Branch Ind He is now said to be quarantined at his home in Fort Branch

Shipwrecked—Dr Perry C Traver South Bend has returned after three months service in the Panama Canal Zone Dr Traver was a passenger on the United States Army Transport *Sumner* which went aground off Barnegat N J, December 11

KENTUCKY

Smallpox—City Health Officer Grant of Louisville recently made the statement that during the eight years preceding 1914 there were reported annually an average of 700 smallpox cases in the city Under the compulsory vaccination law which had resulted in the protection of 30 000 unvaccinated persons the yearly average has been reduced to two cases Similar reductions he said had been noted throughout the state.

Vaccination Decision—In 1916 suit was brought by citizens of Henry County to enjoin the county board of health from enforcing an order of the county board of health requiring all teachers and pupils in the public schools to be vaccinated In a decision by the Court of Appeals of Kentucky, printed in full in *Public Health Reports*, Dec. 29 1916, the court held that the evidence showed that the board was justified in its order that a matter of such vital importance to the community should not be left to the whim of individuals, and that the action of the local board of health should be sustained

LOUISIANA

Dr Dowling Reappointed—Governor Pleasant has reappointed Dr Oscar Dowling Shreveport, president of the Louisiana State Board of Health for a term of four years

MARYLAND

Organization of Bureau of Communicable Diseases—The organization of a bureau of communicable diseases has been announced by Health Commissioner Blake, Baltimore It will be in charge of Dr John F Hogan and will include the health wardens the nursing division the tuberculosis dispensaries school physicians the clerk of vital statistics the fumigation division the complaint clerk, the tenement house division and Sydenham Hospital

Personal—Dr Harry H Johnson has been appointed superintendent of the Sydenham Hospital by Health Commissioner Blake to succeed Dr John F Hogan recently appointed second assistant commissioner of health——Dr Ernest Zueblin professor of medicine at the University of Maryland has accepted the directorship of the tuberculosis department of the medical faculty of the University of Ohio Dr Zueblin is a graduate of the University of Lausanne, Switzerland having entered the institution after five years study at Heidelberg and Zurich——Dr Richard E Yellott Fallston, is in a serious condition at the Hebrew Hospital He is said to have taken several bichlorid tablets while despondent over continued ill health——Dr Simon Flexner of the Rockefeller Institute, New York will deliver a public health lecture on ‘Infantile Paralysis and Its Relation to the Public Health" at a meeting arranged by the Johns Hopkins University and the Women s Civic League December 13 in Baltimore——Dr John C Grieve chief of staff of the Battle Harbor Hospital Labrador delivered an illustrated address recently in Baltimore on the work of the Grenfell Mission in Labrador——Dr Harry L Kolseth has been appointed health warden of the Thirteenth Ward of Baltimore, to succeed Dr John H von Dreele, resigned

MISSISSIPPI

Sanitary Survey of Jones County—The board of supervisors of Jones County will appropriate $1 600 for a sanitary survey of the county to be made in cooperation with the state board of health and the Rockefeller Foundation The latter organization is said to be prepared to spend, if necessary, $50 000 on this work in the county

New Secretary for State Board—At the meeting of the Mississippi State Board of Health January 2 Dr Waller S Leathers university director of public health under the state board and connected with the board for nearly seven years was elected secretary and executive officer to succeed Dr Jacob D Gilleylen, Jackson deceased

New Officers—At the quarterly meeting of the Neshoba-Winston-Newton Tri-County Medical Association held in Newton December 18 the following officers were elected president, Dr Z Carl Hagan Union, vice presidents Drs William H Mars Philadelphia, and Frank L Brantley Dixon and secretary-treasurer, Dr Sidney A Majure, Union (reelected)

NEW YORK

Personal—Dr Marcus B Heyman Central Islip Long Island has been appointed superintendent of the State Hospital for Nervous Diseases Little Rock Ark to succeed Dr Edwin P Bledsoe——Dr William J Gabel Syracuse has been appointed physician to the Onondaga Reservation

Mortality and Morbidity in Syracuse—During 1916 there were in Syracuse 2 360 deaths 63 of which were due to infantile paralysis There were 229 cases of this disease The births numbered 3 875 as compared with 3 577 for 1915 and 3 417 for 1914 The deaths for 1915 were 2,013, and for 1914 they were 2 205 The death rates for the three years were respectively 15.3 13.2 and 14 3 per thousand

Communicable Diseases—At Cohoes during the year ending December 1, there were in the city 490 cases of communicable diseases as follows chickenpox, 10, diphtheria 42 measles 291, mumps, 1 miscellaneous 3 scarlet fever 57, tuberculosis, 70 typhoid fever 11 and whooping cough 5 The record of typhoid fever in the city during the previous six years was as follows 1911, 140 cases, 1912 104, 1913, 20, 1914, 13, 1915, 16 and 1916 11 cases There was no poliomyelitis in the city during the year

County Tuberculosis Hospitals—Nassau County has contracted to purchase a 100-acre tract of land near Farmingdale, L I, and has issued bonds to meet the cost of site and buildings for a county tuberculosis hospital——In Broome and Chautauqua counties sites have been selected for hospitals and in Chenango County construction of a new hospital has been begun——Plans for the new Niagara County Hospital have been filed with the state commissioner of health for his approval——In Rensselaer, Warren and Livingston counties appropriations of $150,000, $50,000 and $35,000, respectively, were carried at the polls last November and the boards of supervisors are now considering sites In Rensselaer County the Albany Railroad has offered to give $150,000 toward the purchase of a site——Rocky Crest, the tuberculosis sanatorium for Cattaraugus County, recently opened is in the town of Olean, between Olean and Rock City The institution has accommodation for twenty-two patients, and Dr Edward Torrey, Olean, is the superintendent

New York City

Deaths from Influenza—Influenza was prevalent during December, and for the week ending December 16 there were 254 deaths from this and other respiratory diseases

Institutions Must Report Puerperal Septicemia and Suppurative Conjunctivitis—The health department will hereafter prosecute all violators of the Sanitary Code, which requires reports from institutions of all cases of puerperal septicemia and suppurative conjunctivitis under their care

Sweeping of Sidewalks Regulated—The board of health has added a section to the Sanitary Code under which house holders are held responsible for the cleanliness of their sidewalks All dirt must be swept up and removed Sweeping into the gutters is prohibited except between 6 and 8 in the morning

Free Dental Clinic for Children—The New York College of Dentistry announces that it will hold a free dental clinic at 205 East Twenty-Third Street, on Saturday afternoons for children between the ages of 7 and 14 There will be ninety chairs available This is the only free dental clinic now maintained by a dental college in this city

Personal—Dr William C Woolsey, Brooklyn, who has recently returned from service on the western war front in France, delivered an address before the Flatbush Medical Society, recently, on "Surgical Treatment of Infection in the French Army"——Dr E P Roberts, New York, has been appointed a member of the New York Board of Education

Alumnae to Meet—The Alumnae of the Woman's Medical College of the New York Infirmary for Women and Children will have a reunion dinner at the McAlpin Hotel, Monday evening, June 4, during the week of the meeting of the American Medical Association Further information may be obtained by communicating with the secretary of the Reunion Committee, Dr Ethel D Brown, 26 Gramercy Park

Fund for After-Care—Health Commissioner Emerson has turned over to the New York Committee on After-Care of Infantile Paralysis $39,287 60 to be added to the fund of $250,000 which the committee started out to raise This sum is the unspent balance of contributions made in August, 1916, on an appeal by the health department for funds to purchase braces and other appliances for children crippled by infantile paralysis

Bronx Doctors Raise Fees—The Bronx County Medical Society announces that physicians of the Bronx have adopted a new schedule of fees, under which night calls or emergency calls during the day will be $4 Calls during office hours requiring a doctor to leave his office before his accustomed time will be $3 Day calls will be $2, and office calls not less than $1 A like charge will be made for information given over the telephone

Institute Votes Special Compensation—The trustees of the Rockefeller Institute for Medical Research, in consideration of the decrease in the purchasing power of fixed salaries caused by the increased cost of living, voted additional and special compensation equal to 15 per cent of the current annual salary to be paid to each regular officer and employee of the institute, it being understood that this is not an increase in salary and does not create a precedent for the future Employees who have served less than one year are to be paid 15 per cent of the amount actually received up to the last day of December, 1916

City's Death Rate for 1916—Notwithstanding the epidemic of influenza and infectious colds, and the epidemic of poliomyelitis, during 1916, the death rate for the year is the lowest on record, 13 89 per thousand In 1900 the death rate was 20 57, and in 1910 16 00 This lowering of the death rate has been accomplished through the reduction in infant mortality In 1910 the death rate per thousand infants born was 125 6, during 1916 it was 93 1 The death rate from typhoid in 1910 was 0 12, and in 1916, 0 04 In 1912 there were seventy deaths from poliomyelitis, in 1913, fifty-four, in 1914, thirty-four, in 1915, thirteen and in 1916, 2,248 The death rate from pneumonia in all forms was in 1913, 0 13, and in 1916, 0 14 In 1900, the death rate from tuberculosis was 2 37, in 1910, 1 81 and in 1916, 1 50 The common infectious diseases of childhood have all shown a remarkable decrease, while the diseases of adult life, organic heart disease, nephritis and cancer, show proportionately more deaths than they did ten years ago The marriage rate for the year was 9 78, as against 9 68 for 1910 and 9 33 for 1915 A study of the marriage death and birth rates of the past ten years has convinced the recorder that the estimated population of the city, 5 602,841, is approximately correct

NORTH CAROLINA

District Society Meeting—At the annual meeting of the Fourth District Medical Society, held in Wilson, the following officers were elected president, Dr Kinchin C Moore, Wilson, vice presidents, Drs James C Grady, Kenly, and Edmund S Boice, Rocky Mount, secretary, Dr Charles L Swindell, Wilson, and treasurer, Dr Henry B Best, Wilson

Secret Medicine and Liquor Business—The January issue of the *Bulletin of the State Board of Health* is devoted entirely to the secret medicine business It is hoped that the next legislature, encouraged by the prohibition forces of the state may enact legislation relative to the sale of secret remedies which have become so frequently cloaks for the sale of diluted alcohol in the prohibition states of the South

OKLAHOMA

Endorse University Hospital—At the meeting of the Tulsa County Medical Society at the Oklahoma Hospital, December 18 a resolution was adopted to endorse the efforts of the administration to build and equip a hospital at Oklahoma City, to cost $200 000 and to be conducted under the supervision of the medical department of the state university

Personal—Dr Pleasant M Haraway, Marlow, was recently injured by a fall downstairs——Dr Horace Reed Oklahoma City, has recovered after an operation for appendicitis——Dr John H Harms and wife were recently injured when their automobile was driven into an open bridge——Dr Albert C Hirschfield, Oklahoma City, who is stationed on the border with the Oklahoma militia, recently fractured his thigh——Dr Welcome B Tilton, Clinton, has been appointed physician to the Uintah and Ouray Indian reservation, at Fort Duchesne Utah——Dr James G Rafter, Muskogee, city physician, was severely injured when his automobile was struck by a street car

OREGON

New Hospital Assured—The department of medicine of the University of Oregon has succeeded in raising by subscription, the $25,000 necessary to secure the $50,000 appropriated by the Oregon legislature a year ago This sum is to be expended in building a hospital on the medical school's new campus on Marquam Hill, overlooking Portland

New Health Board Officers—At the annual meeting of the state board of health, held in Salem, December 21 Dr Alvane C Seely, Roseburg was elected chairman, and Dr David N Roberg, Portland, was reelected secretary and state officer One of the most important features of the session was the subdivision of the board of health registration districts of the state under the acts of 1915 Two hundred and forty-eight subdivisions were made under this act

New Officers—The Portland City and County Medical Society at its annual meeting, December 20, elected the following officers president, Dr Joseph M Short, vice president, Dr Clarence J McCusker, secretary, Dr J Guy Strohm (reelected), and treasurer, Dr Katherine C Manion (reelected)——At the annual meeting of the Central Willamette Medical Association, held in Albany, December 7, Dr James H Robnett, Albany, was elected president, Dr Edward Bennett, Monroe, vice president, and Dr Gerald E Riggs, Albany, secretary-treasurer

PENNSYLVANIA

Health Commissioner's Secretary Resigns—Mr H Lindley Hosford, secretary to Dr Samuel G Dixon state commissioner of health has resigned to take charge of an educational campaign to be conducted in New York state

Smallpox Epidemic—Sporadic cases of smallpox have been reported from Allegheny County for several weeks and in the last two days three or four cases have been reported Assistant Chief Medical Inspector Hull of the state health department has been sent to Pittsburgh Two thousand five hundred notices were sent to physicians, school boards health boards and large employers of labor, and vaccination under the direction of the department of health has been started on a large scale

Personal—Dr William H Robinson, Roaring Springs fell on a pavement December 13 sustaining a concussion of the brain He is under treatment in the Mason Hospital——Dr Walter Lathrop was reelected surgeon and superintendent of the Hazleton State Hospital for the twentieth time, December 8 Dr Robert A Gaughan has been reelected assistant superintendent——Dr William S O Sherman Pittsburgh delivered an illustrated address before the Mahoning County Medical Society Youngstown Ohio on 'The Methods of Wound Treatment and Sterilization as Practiced in the French Army '

Philadelphia

Inspection Force Reduced—Because their services were no longer required twenty-seven medical inspectors and thirty-two nurses engaged by the bureau of health last summer during the prevalence of anterior poliomyelitis, have been discharged

Professorship Endowed—Miss Anna J Magee has presented to Jefferson Medical College $150 000 to endow the Magee professorship of the practice of medicine and clinical medicine Dr Thomas McCrae has been appointed to the newly endowed chair

After-Care of Paralysis Victims—The Emergency Aid organization has asked for $20,000 to carry out the after-treatment of 492 children crippled by poliomyelitis during 1916 Many of the victims need expensive braces and appliances Three hundred are receiving dispensary treatment, while the other 192 are being treated at hospitals

Personal—Dr Richard M Pearce Jr of the University of Pennsylvania will sail from New York January 15 to make a medical survey of the Argentine Republic and Uruguay——A fire in the home of Dr William W Keen January 2 caused much excitement, but little damage——Director Wilmer Krusen of the Department of Public Health and Charities was presented with a large grandfather s clock by the chiefs of bureaus and the employees of the department

Teaching Force Depleted by Pneumonia—Pneumonia and grip have so depleted the teaching force of the Philadelphia public school that the entire substitute list has been exhausted and thirty-eight classes are without teachers Reports of deaths from pneumonia during the last two weeks show the epidemic thus far has proved more fatal to adults than to children under 16 There were 167 deaths from lobar pneumonia as compared with sixty deaths from bronchial pneumonia

Medical Institutions—An addition to Bryn Mawr Hospital is to be two and one-half stories in height and will be of stone——A union between the Child Federation and the Public Education and Child Labor associations was formed January 1 to be known as the Child Federation The offices will be in the Witherspoon Building Albert Cross executive secretary of the Child Federation will be managing director and secretary of the combined organization It is hoped to reduce administration expenses so that more money will actually go into the work among children

Officers Elected—At the meeting of the Section on Otology and Laryngology College of Physicians Dr George C Stout was reelected chairman and Dr George M Coates clerk for the ensuing year——The West Philadelphia Medical Association has elected the following officers for 1917 president Dr William S Newcomet, vice president Dr Charles E Price, secretary Dr Henry G Munson, treasurer Dr Edmund L Graf and additional members of the board of directors to serve three years Drs Aaron L Bishop, Seth A Brumm, George F Levan and Justus Sinexon——At the meeting held January 3 the following officers and elective committees were chosen by the College of Physicians of Philadelphia for 1917 president Dr Richard H Harte vice president, Dr William J Taylor, censors Drs James Tyson William W Keen George E de Schweinitz and Thomas R Neilson, secretary Dr Francis R. Packard and treasurer, Dr John B Roberts

VIRGINIA

Marine Hospital for Norfolk—Hon E E Holland M C introduced a bill in the House of Representatives, December 21 appropriating $500 000 for a marine hospital at Norfolk

Memorial to Dr Johnston—The Richmond Academy of Medicine and Surgery December 23 adopted memorial resolutions regarding the death of Dr George Ben Johnston

Personal—Dr Hampden A Burke. Petersburg has been appointed a member of the State Board of Medical Examiners for the Fourth District, succeeding the late Dr Otho C Wright Jarratt

Medical Society Organized—The Bath County Medical Society having been granted a charter by the Medical Society of Virginia a meeting for permanent organization was called at Hot Springs December 27 at which Dr Lanier D Pole Hot Springs presided as temporary chairman and Dr Guy Hinsdale Hot Springs was temporary secretary

Contract for Hospital Awarded—The contract for the erection of the new negro pavillion of the Memorial Hospital Richmond has been awarded The building will cost when completed and equipped about $175 000 It is expected that it will be finished by November 1 It is to be seven stories and a basement in height and will contain accommodation for 146 patients forty in private rooms and 106 in wards

New Officers—At the annual meeting of the Richmond Academy of Medicine and Surgery December 12 the following officers were elected president Dr Greer Baughman vice presidents Drs Claude C Coleman William R Weisiger and Marvin E Nuckols, secretary Dr Mark W Peyser (reelected for the twenty-fourth consecutive term) assistant secretary Dr Emmett H Terrell and treasurer Dr James H Smith all of Richmond——At the fifty-fifth annual session of the South Side Virginia Medical Association held in Petersburg December 12 the following officers were elected president Dr Joel Crawford Yale, vice presidents Drs Fletcher J Wright Petersburg, James H Hargrave Hopewell and Edgar W Young McKenney and secretary-treasurer Dr Emmett F Reese Courtland Hopewell was selected as the next place of meeting

GENERAL

Physical Directors Elect Officers—At the meeting of the Society of Directors of Physical Education and Colleges held in New York December 29 Dr Joseph E Raycroft Princeton N J, was elected president Dr Edwin Fauver Rochester University vice president and Dr Paul C Phillips Amherst Mass secretary-treasurer (reelected)

Big Four Surgeons Hold Meeting—At the annual meeting of the Big Four Railway Surgeons Association held in Cincinnati December 14 the following officers were elected president Dr Granville Reynard Union City, Ind , vice presidents Drs Edward R Henning Bellefontaine Ind , James T Musselman Paris Ill and Adoniram J Banker, Columbus Ind and secretary-treasurer Dr William A Ewing Dayton Ohio

Tri-State Physicians Meet—At the thirteenth annual session of the Tri-State Medical Society of Arkansas Louisiana and Texas at Texarkana Ark December 19 Shreveport La was selected as the next place of meeting and the following officers were elected president Dr Jacob M Bodenheimer Shreveport vice presidents for Arkansas Dr Thomas F Kittrell Texarkana for Louisiana Dr Thomas E Wright Monroe and for Texas Dr Charles M Rosser Dallas, and secretary-treasurer Dr Edwin L Beck Texarkana

Large Amounts Needed for Charities—A campaign is in progress to raise $150 000 to enlarge the Norwegian Lutheran Deaconess Home and Hospital Chicago——Nearly $2 500 000 for the relief of Jewish war sufferers in Europe was pledged at a mass meeting in Carnegie Hall New York December 21——Jewish women of the United States under the leadership of Hadassah have inaugurated a campaign to raise $100 000 for a medical unit to be dispatched to Palestine to combat infectious disease and to improve sanitary conditions

Elections in Surgical Societies—At the annual meeting of the Southern Surgical and Gynecological Society, held in White Sulphur Springs W Va December 13 Dr William

D Haggard, Nashville, was elected president The society will meet next year at St Augustine, Fla ——At the twenty-sixth annual meeting of the Western Surgical Association, held in Minneapolis, December 16, the following officers were elected president, Dr Leonard Freeman, Denver, vice presidents, Drs Joseph Ransohoff, Cincinnati, and Roland Hill, St Louis, and secretary-treasurer, Dr Arthur T Mann, Minneapolis Omaha was selected as the next place of meeting

Civil Service Examination—The United States Civil Service Commission announces an open competitive examination for assistant epidemiologist (male), to be held January 30 From the eligible list certification will be made to fill the vacancy in the Public Health Service, with a salary ranging from $2 000 to $2,500 per year Applicants must be citizens of the United States, between 23 and 40 years of age, graduates of medical schools of recognized standing and must have had at least three years' experience in epidemiologic work under federal, state or local authorities, and experience in laboratory technic with special reference to malaria and typhoid fever

Bequests and Donations—The following bequests and donations have recently been announced

St Luke s Hospital New York, $5,000 by the will of Mary C Elmendorf

Flagler Hospital St Augustine Fla Germantown (Pa) Dispensary and Hospital Morristown (N J) Hospital Babies Hospital, New York and St Mary s Hospital for Children New York, each $100 000 and St John s Guild, New York $50,000 by the will of Mrs Charles W Harkness

Hahnemann College and Hospital Philadelphia, a bequest of $40 000 by the will of Marcus N Darr, Buffalo N Y

Exeter (N H) Cottage Hospital a bequest of $10 000 by the will of Abner L Merrill Exeter

Children s Hospital Milwaukee, a donation of $150 000 from Ferdinand Schlesinger contingent on the raising of a like sum by the hospital association and $5 000, the receipts of a Horse Show held in Milwaukee December 20

New Journal Issued—The Rhode Island *Medical Journal*, owned and published by the Rhode Island State Medical Society has issued its first number under date of January, 1917 This new state journal succeeds the *Providence Medical Journal* published by the Providence Medical Association It will be issued monthly instead of bimonthly On an editorial page of this first issue it declares that 'it is a source of satisfaction in which every reader can share that the advertising pages of this journal are as clean as those of any medical publication in the country " The *Providence Medical Journal* first appeared in January, 1900 It has been edited during the sixteen years of existence by Drs George S Hershey, F T Rogers and J W Leech The editor of the new journal is Dr Roland Hammond On the editorial staff are Drs F T Rogers, J W Leech Alexander M Burgess and John E Donley Dr J F Hawkins is the business manager

Wellcome Prizes—The Association of Military Surgeons of the United States announced, January 5, the results of the Henry S Wellcome prize competition A gold medal and $300 were awarded to Capt Mahlon Ashford, M C, U S Army, for his essay entitled "The Most Practicable Plan for the Organization, Training and Utilization of the Medical Officers of the Medical Reserve Corps, of the U S Army, and of the Medical Officers of the Officers' Reserve Corps of the U S Army, in Peace and War" Asst Surg Gen William Colby Rucker, U S P H S, was awarded a silver medal and $200 for his essay, "The Influence of the European War on the Transmission of Infectious Diseases, with Special Reference to Its Effect on Disease Conditions in the United States" Lieut Henry C Coe M R C, U S Army, New York, and P A Surg James R Hurley, U S P H S, each received honorable mention and a life membership in the association

Fraudulent Drug Traffic Checked—Fraudulent traffic in imitations of certain synthetic drugs used extensively by physicians has been checked through the joint action of federal, state and municipal officials, according to the annual report of the Chief of the Bureau of Chemistry, United States Department of Agriculture Because of the high prices demanded for such drugs, cheap imitations, with little or none of the therapeutic properties of the genuine, have been put on the market under the names and labels of the real drugs Shipments were seized, and a number of individuals were prosecuted successfully, under the Federal Food and Drugs Act, and indictments were procured under the postal laws, but the traffic could not be wholly suppressed under the federal laws, nor could all offenders be reached The department of agriculture thereupon laid the matter before the state and municipal officials, with the result that many prosecutions were instituted and seizures made by them Ultimately, through joint action, the traffic was suppressed

Conference on Medical Preparedness—At the request of the Council of National Defense and the secretary of war, deans and representatives from more than eighty medical schools of the country convened in Washington January 6 The preliminary meeting was called to order by Dr Franklin H Martin, Chicago, who stated that the object of the meeting was to agree on some basis of cooperation between the medical schools of the country and the army and navy, whereby the depleted medical branches of the service might be recruited to full strength from the eligible graduates of the medical schools this summer Dr Edward Martin of the University of Pennsylvania was called to the chair and introduced Surgeons-General Gorgas and Braisted, who set forth the needs of the army and navy medical departments Plans for courses on military and naval surgery were presented by Col William H Arthur, director of the Army Medical School, and Surg Edward R Stitt of the Navy Medical School The curriculum provides for two lectures a week, the course to begin on February 1 Dr Victor C Vaughan of the University of Michigan presented a resolution favoring universal military training and petitioning the secretaries of war and of the navy to supply the medical schools with instructors on medical surgery and sanitation Dr Arthur A Law of the University of Minnesota presented a resolution petitioning Congress to modify the army act of June 3, 1916, so as to make express provision for the detailing of medical officers of the army as instructors in military surgery and hygiene in medical colleges Both of these resolutions were adopted Major Robert E Noble of the army presented the needs of the Medical Corps and stated that by July, 1920 the army would need 1 110 medical officers to complete its full quota In the afternoon, the members of the conference were received by the president and secretaries of war and of the navy Secretary Baker welcomed the officers and thanked them for their interest in medical preparedness

FOREIGN

No Importation of "Patent Medicines" Into Germany—The *Munchener medizinische Wochenschrift* cites a recent official order to the effect that the decree of Feb 25, 1916 prohibiting importation of unnecessary articles (*entbehrliche Gegenstande*), applies until further notice to proprietaries (*Geheimmitteln*)

Journal Founded as Official Organ of Welfare Work for Disabled Soldiers—The affiliated agencies throughout the German empire working to improve the condition of those maimed and crippled by the war have combined and the central board is issuing a monthly to serve as the forum for all matters of the kind and possibly to serve later as a general forum for welfare work of all kinds The editorial staff consists of A Liebreich, Magistratsrat in Berlin, and W Gerth, Amtsrichter L Voss of Berlin is the publisher, the yearly subscription is about $4

Public Education on Disease—The *Deutsche medizinische Wochenschrift* states that even during the war the demands continue for loans of the collections at the central headquarters at Berlin of the medical postgraduate instruction system Many requests come from the countries now occupied by troops The collections are loaned free of charge for popular lectures given by nurses hygienists and others, as well as by physicians Lantern slides and wall pictures are most in demand, especially sets of slides on venereal diseases, bacteriology, care of the sick, anatomy, prophylaxis and care of the health in general, tuberculosis, epidemics, etc A special catalog is sent on demand The headquarters of the postgraduate work are at the Kaiserin Friedrich-Haus, Luisenplatz 2, Berlin

Alvarenga and Jubilee Prizes Awarded in Sweden—The Alvarenga prize is awarded annually by the Swedish Medical Association The 1916 prize was given to Dr E Nilsson for his comprehensive study of the physical development and fitness for military service of the young men of Sweden between 1861 to 1913 The association distributed eleven other prizes The jubilee prize was given to H B Lundborg for his medical-biologic study of generations of certain families in Sweden totaling 2,232 members He traced the working of the mendelian laws of heredity through nearly 200 years A work by Lundborg on this topic of race hygiene and its importance in modern culture was published in the *Journal of Nervous and Mental Disease*, 1912, No 11, p 39 The Journal, June 15, 1912, p 1890, also summarized some of his research on deafmutism in 414 families

CANADA

Infantile Paralysis Disappearing in Ontario—Only five cases of infantile paralysis with one death were reported in December in the Province of Ontario, as compared with seventy-six cases and seven deaths in September, thirty-one cases and seven deaths in October, and ten cases and two deaths in November

Medical Inspection of Schools in Toronto—The vote on the amalgamation of the medical inspection department of the Board of Education, Toronto, with the Department of Public Health, January 1, resulted in a majority of nearly 14 000 for the amalgamation It will be necessary for the Toronto City Council to secure the sanction of the Ontario legislature to the vote of the people before amalgamation is finally effected Last year the city council unanimously approved of the amalgamation The vote for amalgamation stood as 3½ 1

Personal—Col James A Roberts, Toronto, in command, of the University of Toronto Base Hospital, Saloniki, and Col Herbert S Birkett Montreal, have been made Companions of the Bath——Capt J Harris McPhedran, Toronto, on leave of absence, has sailed for England——Capt D Edwin Robertson, Toronto, who has been on active service for over two years, has arrived home and will reenter professional life He will be first assistant to Dr W Edward Gallie, who has been chief surgeon at the Hospital for Sick Children, Toronto, since the departure of Dr Clarence L Starr for special operative work in London——Dr Walter W Wright, Toronto, has enlisted for overseas service

University News—The Senate of Queen's University, Kingston Ont, has issued a memorandum covering its objections to the action of the University of Toronto in deciding to establish in 1918 a six-year academic course in medicine A conference had been held between representatives of the two universities but no other universities interested in Canada had been asked to participate in that conference Queen's University says that the proposals come at a time when there is an unusual demand for the services of medical men from the British and Canadian governments, and that the great need for medical men will not immediately cease when war is over

Colonel Bruce Not Upheld—The official report of the Board of Inquiry into the report and charges of Col Herbert A Bruce, Toronto, who went overseas last July, deputed by the Canadian government, or the Minister of Militia of that day, as Inspector General, to make an exhaustive inquiry into the condition of the army medical services of Canada and the Canadian hospitals abroad, has just been, made public by the Canadian High Commissioner It upholds Surg-Gen G Carleton Jones, and states that the charges made by Colonel Bruce have not been substantiated, nor does the Board of Inquiry consider that the changes recommended in Dr Bruce's report are necessary or advisable The announcement is made in the public press that Colonel Bruce is returning to Toronto, and that Surgeon-General Jones will at once reassume his command

Workmen's Compensation and the Doctors' and Hospital Fees—Representatives of the Ontario Medical Council, the Ontario Medical Association and the Academy of Medicine, Toronto, joined with representatives of the labor interests on January 5 to discuss the payment of doctors' and hospital fees by the Workmen's Compensation Board, before the Private Bills Committee of the Ontario legislature The manufacturing interests were also represented Dr Edmund E King, president of the Ontario Medical Council, presented the case for the physicians and stated that the profession was far worse off under the commission than previously, when practically all employers paid the professional bills of employees injured in their work The labor interests unanimously supported the physicians in asking that these bills be paid by the commission The manufacturers, of course, opposed the proposition, as it would mean a greater assessment on the industries The government made no announcement as to its intention to amend the bill in the direction sought but the prime minister of the province appeared sympathetic The total number of accidents in the province during the past year was 26,092

LONDON LETTER

London, Dec 18, 1916

The War

FOOD CONTROL

The continuance of the war has created some difficulty with regard to the supply of food, but this is much less acute and has developed much later than in Germany A food controller has been appointed, and the following legislation is expected soon 1 Meat Institution of a compulsory meatless day, Thursday will probably be the day selected On that day it will be unlawful for any person to sell or consume, either in places of public eating or in private houses, meat, game and poultry It is understood that fish will not be included in the order 2 Sugar "Rationing" by the state, probably by a system of tickets There is enough sugar to go round at present, it is the old system of distribution that is at fault 3 Bread Maize, barley and oats to be included among the ingredients for baking Maize blends most easily, barley is the most palatable, and oats the most nutritious of the three There may not be much maize to spare, as it can be put to other and even better uses in our present situation 4 Potatoes A big program of saving to be undertaken to insure next season s supplies 5 Pigs As urgent a matter as potatoes, both provide a great part of the staple food of the working classes Special steps are to be taken to increase largely the number of pigs in this country The space to be allotted to the transport of tea will in future be much curtailed

VITAL STATISTICS

Vital statistics during the disturbing influence of the greatest of all wars are of special interest The quarterly return of the registrar general for the three months ending with September have just been issued The birth rate has shown a slight rise It is now 21 7 per thousand of the population, as compared with 19 5 the rate in the fourth quarter of 1915, which was described as the lowest birth rate recorded in any quarter since the establishment of civil registration The deaths registered amounted to 102 457 civilian and noncivilian This is a rate per thousand of 11 2 Infant mortality, measured by the proportion of deaths under 1 year to registered births, was equal to 79 per thousand, being 41 per thousand below the average in the ten preceding third quarters, and equal to the lowest recorded quarterly rate, namely, that for the September quarter, 1912

Abolition of Compulsory Latin for Medical Students

The preliminary examination which every youth must pass before being registered as a medical student included Latin as a compulsory subject The modern tendency to exalt science at the expense of the classics has brought about a position which has compelled the General Medical Council no longer to require a knowledge of Latin—which was usually very elementary—by medical students For fourteen years the University of London has not required Latin for its matriculation examination, and within the last two years the Universities of Liverpool, Leeds, Sheffield and Birmingham have followed The medical council was therefore in the anomalous position of requiring knowledge of a subject which these universities do not require of students undertaking medical or other courses After an animated debate in which several speakers insisted on the great advantage of a knowledge of Latin to the student in his medical studies, the council decided by a majority of 21 to 12 to accept the examinations of these universities This conclusion was something of a compromise, for Latin still remains compulsory for what are called "junior grade" candidates for admission to the medical curriculum These are boys who usually leave school at an earlier age than the "senior grade' candidates mentioned above and do not produce, as evidence of general knowledge certificates of examination by a university Latin is retained as a compulsory subject for them on the ground that there is at present no satisfactory substitute for that language in the educational scheme suitable to a boy of 15 The contribution to the discussion at the medical council of a brilliant scholar in the wide sense, Sir Clifford Allbutt, is worthy of attention He said that for years he had been against any particular subject being made compulsory for entrance It was perfectly amazing how boys wriggle through an examination in Latin and Greek with so little knowledge of either, and the time devoted to them was not worth it If the average man was asked to translate or go behind the Latin words he had used, it would be found they had been used in a parrot like way and learned by heart as ladies learn the names of plants What was desired was to raise the literary quality of teaching, which could be attained by substituting two modern languages—French and Italian or French and Spanish—for Latin, so that the students would come up with a fair amount of literary cultivation

A Leper in a Lodging House

In the court of appeal, a point of interest to the profession has been decided An action was brought by a lodging house keeper against a physician and a woman for fraudulent representation and conspiracy The latter engaged rooms for her father, who was a leper and died from the disease after a year The plaintiff alleged that she had suffered damage in consequence In answer to her question, the leper's physician said that he was not suffering from an infectious disease but that great care should be taken He believed that leprosy was not infectious In answer to questions put by the judge, the jury decided that leprosy was infectious and that the defendants had by fraudulent misrepresentation induced the plaintiff to admit the leper They assessed damages at $1,250 After argument, however the judge held that the defendants were entitled to judgment because there was no implied term or warranty in the compact of tenancy that the leper was a fit and proper person to occupy the rooms, and that the physician was not bound in law to make any disclosure as to the condition of the patient This judgment has been upheld by the judges of the court of appeal

Anthrax in Shaving Brushes

An account was recently given (The Journal, Sept 30 1916, p 1030) of cases of anthrax due to contaminated shaving brushes The subject has again arisen in Liverpool, where two specimen shaving brushes infected with anthrax have been discovered At a meeting of the Liverpool health committee, Dr Hope health officer, said that the hairs of which brushes were made had probably been taken from infected skins All brushes of the kind which could be found in the city had been taken and destroyed One of the brushes had been discovered in a curious way A man bought it in Liverpool and used it on the way to Halifax, N S When he arrived there he was found to be suffering from anthrax, and the fact was reported to Liverpool A number of the brushes had then been bought Their origin had been traced *to foreign firms on the continent*

PARIS LETTER

Paris, Dec 14, 1916

The War

TREATMENT OF WOUNDS OF THE KNEE

Professor Depage of Brussels has just reported to the Societe de chirurgie de Paris statistics of 124 wounds of the knee treated at the ambulance hospital 'Ocean," at La Panne since Dec 20, 1914 Eighty-three were serious cases, which he classifies in two categories (1) wounds without large separation of the joints and without very serious lesions of the bone extremities, and (2) wounds of the joints with serious and wide lesions of the bone extremities

These wounds have been treated in various ways Until Sept 10, 1915, Depage drained the joints during a longer or shorter period, after the cleansing and excision of torn tissues, making one or several dressings every day In each instance the wound was irrigated with antiseptic solutions (oxygenated water, formaldehyd or phenol [carbolic acid]) The wounded limb was kept rigid either by a bridged apparatus or by a drain During a second period, until July 1, 1916, Depage applied the method of Carrel after ample loosening of the joints During a third period he practiced systematically the immediate closing of the joints of the knee despite extensive lesions of the bone Until that time he had sutured the synovial membrane immediately only in articular wounds of the knee without lesions of the bone After a careful dressing of the region, the wounded and bruised tissues were excised, the bullet or foreign matter removed, the joints freely washed with Dakin s solution or with ether, and the bones curetted or scraped with a gouge, a small rubber drain being left in the joints for twenty-four hours in contact with the lesions of the bone By some means immobility was secured When this method is employed, the temperature is generally about 37 5 C (99 5 F) on the evening of the operation, in two or three days it returns to normal *in eight days massage* is begun with passive movements, and in fifteen days the patient is given a mechanotherapeutic course of treatment In certain cases, however, the temperature climbs to 38 C (100 4 F) and even 38 5 C (101 3 F) *The local condition then dictates the course to be followed* If the joints do not show any reaction, further treatment is deferred and order is generally restored within five or six days If infection appears certain, arthrotomy is resorted to, and the Carrel treatment is given when the lesions of the bone are not too extensive If, on the other hand, these lesions are serious, resection is made without delay

The value of the three methods successively employed by Depage in the treatment of articular wounds of the knee is clearly shown in the following table

	First Period 29 Wounds Per cent	Second Period 32 Wounds (Carrel Method) Per cent	Third Period 22 Wound (Closing of Wound) Per cent
1 Cures with restitution of movements	24 10	46 87	86 36
2 Suppurations of the knee	68 80	28 12	4 54
3 Ankylosis with or without resection	37 93	18 75	13 63
4 Amputations of the thigh	34 40	15 62	0
5 Deaths	13 88	3 06	0

TREATMENT OF WOUNDS OF THE BREAST

In accordance with an opinion still too much in vogue it is believed that most penetrating wounds of the thorax heal *without the employment of operative treatment Drs Combier* and Murard have voiced their disapproval to the Societe de chirurgie de Paris They have shown that the death rate among the wounded so treated is considerable, at least among those with large wounds in which hemorrhage shows no tendency whatever to cease, as these patients lose too much blood Combier and Murard have also tried to intervene in these cases by suture of the bleeding lung and suppression of the pneumothorax In three particularly threatening cases they have employed successfully the following mode of treatment resection, under local anesthesia, or a simple injection of morphin, of the fractured ribs on an area just wide enough to furnish ready access to the lung, exteriorization and exploration of the affected pulmonary lobe, which usually is easily performed, suture of the pulmonary wound with the aid of long U-shaped points, anchoring of the sutured wound to the interior surface of the thorax, if possible, so as to permit the lung to recuperate its play , drainage by means of a tampon of the membrane lining the interior of the ribs The thoracic lining could also be entirely sutured without tamponing by making an incision for breathing in case of pleural effusion There are, however, more favorable methods, which are successful in less serious cases such as simple occlusion of the wound with a suture, employed by old school surgeons In wounds in which the air comes in contact with the membrane lining the interior of the ribs, it is sufficient simply to close the wound to prevent infection treating it as a simple pneumothorax requiring rapid resorption This procedure has often given Combier and Murard good results

Relative to this report, Drs Rochard, Delorme and Baudet remind us that they had ceased, long before the war, to oppose operative treatment in serious cases of wounds of the breast

THE TREATMENT OF SHOCK IN WAR SURGERY

Professor Depage of Brussels has made a report on this subject to the Societe de chirurgie de Paris He points out that vasoparalysis constitutes one of the most important phenomena of shock The circulatory field becomes too large for the quantity of blood in the veins, the function of the heart becomes impaired, blood accumulates in the arteries and the blood pressure becomes lower as the extremities become cold and cyanotic The treatment of shock calls for (1) a special position of the patient in which the abdominal vessels are at a higher level than the heart and the brain (this necessitates merely adjustment of his bed, (2) heat, (3) restoration of blood pressure to a sufficiently high degree either by increasing the quantity of the blood fluid (injection of Locke's serum), or by determining the vascular constriction (digitalis, strychnin, camphorated oil)

VESICAL CALCULI IN WOUNDS OF THE BLADDER

Dr Legueu, clinical professor of diseases of the urinary tract of the Faculte de medicine de Paris has pointed out to the Academie de medecine that about one third of the wounds of the bladder develop one or more calculi within a few months Legueu estimates that these calculi have less to do with infection than with a concomitant fracture of the pelvis, such as is found in all wounds developing calculi While serious disorders are given attention, fragments and splinters of bone frequently fall into the bladder, so that after the healing of all exterior wounds one finds an internal osteopathic abscess visible only with a cystoscope For some time the cavity of the bladder continues to receive from the focus of the fracture minute particles of bone which enter the bladder, causing calculi Hence the osteovesicular abscess is the primary lesion from which complications result Legueu has attempted operative treatment for these abscesses, but the disorders necessarily caused in healing them are very complicated and postpone the patient's recovery several months He has relieved a patient of his calculus in a few days by lithotrity and he advises that the abscess be permitted to close itself spontaneously

NEEDLE WOUND OF THE HEART

Dr Marais reported to the Societe de chirurgie de Paris the case of a soldier who thrust a needle into his heart with the intention of killing himself and who died suddenly twenty-four hours later without having shown any sign of internal hemorrhage in the meantime. At the necropsy there were found an abundant hemorrhagic infiltration in the anterior mediastinum and an infusion of 120 gm of blood in the pericardium In the middle of the latter infusion was found the needle which had caused death No trace of its passage was visible on the skin On the anterior surface of the right ventricle was a wound 4 cm long and 2 5 cm in average width It was a superficial wound above but deep and penetrating in the lower part. This leads one to suppose that the needle after having perforated successively the thoracic wall and the pericardium (the victim was very thin), was maintained in place by one extremity in the thoracic wall, while the other extremity worked its way through the myocardium causing a slow, insignificant hemorrhage with no clinical signs, which later suddenly became abundant and fatal Marais was of the opinion that if the diagnosis had been made earlier, surgical intervention would probably have been successful

Reorganization of Physical Education in Public Instruction

A commission has just been instituted at the ministry of the interior for the purpose of studying the reorganization of physical education in public instruction Among the members of this commission are Drs Gilbert and Weiss professors of the Faculte de medicine de Paris, and Henri Mery, Albert Mathieu and Mosny, physicians at the hospitals of Paris

The Decimal Classification in the Numbering of Surgical Matter

The military health service has just systematized part of its surgical matter by introducing the decimal classification at the suggestion of Mr Paul Woog Until recently, when a very fine catgut ligature was desired specifications were given for triple zero' 'double zero or single zero" depending on whether the diameter of the catgut was 0 2, 0 3 or 0 4 mm A silk ligature of 0 3 mm was designated as No 2 in the health service and was called zero in the civil service. An O' drain measured 4 mm in exterior diameter and a No 6 drain, 20 mm This illogical and complicated classification has recently been replaced by a simple and rational one The figures adopted for catgut silk ligatures drains and rubber tubes will designate in tenths of a millimeter the outside diameter of these objects Thus a No 6 ligature is six tenths or 0 6 mm in diameter a No 10 ten tenths, or 1 mm in diameter, a No 130 drain will be 130 tenths or 13 mm in diameter, etc

---

Marriages

Manley Hunter Eames M D Oak, Va to Miss Mary Virgilia Warburton of Williamsburg Va at Richmond, Va December 18

Robert Parke Bay M D, Baltimore to Miss Nancy M McNabb of Harford County, Md., at Baltimore December 23

Grover Cleveland Goudy M D, Canton Ohio, to Miss Edna Amanda Hilger of Pittsburgh December 30

Clyde James Bibb M D, to Miss May Hollern, both of Portage Pa at Hollidaysburg Pa November 5

Irving William Fraim M D, Waltham Mass, to Miss Leola Basley of Worcester Mass, December 19

Gustav Kolischer, M D Chicago, to Miss Juliette Lippe of New York December 26

Frederick G Fox M D to Miss Anna Kuehn both of Chicago December 31

Deaths

Arthur Curtis Rogers, M D, Faribault, Minn , a pioneer and leader in the work for defectives, died in the University Hospital Minneapolis, January 2, from pernicious anemia Dr Rogers was born near Decorah, Iowa July 17, 1856 After graduation from Earlham College, Richmond, Ind, he taught school and then became steward of the State School for Feebleminded, Glenwood, Iowa His interest in the work caused him to take up the study of medicine in the State University of Iowa, Iowa City, from which he was graduated in 1883 He went to Oregon as head physician and principal of the State School for Indians, Forest Grove, and two years later was called to Minnesota to become superintendent of the Minnesota School for Feebleminded and Colony for Epileptics at Faribault a position which he held until the time of his death The institution which then had about fifty inmates now employs about 300 teachers and attendants, cares for more than 1 600 inmates and has been regarded for many years as one of the model institutions of the country Dr Rogers was a Fellow of the American Medical Association president of the Minnesota Conference of Charities and Correction in 1898 and of the Minnesota Academy of Social Science in 1911 He was secretary and treasurer of the American Association for the Study of the Feebleminded and a member of the commission to revise Minnesota laws relating to children

Hon Sir Frederick William Borden, K C M G, minister of militia and defense of Canada from 1898 to 1911, died at his home in Canning N S January 6 He was born May 14, 1847 the son of Dr J and Maria F Borden His preliminary education was received at the University of Kings College, Windsor, N S, and his medical course was taken at Harvard Medical School, from which he was graduated in 1868 He was appointed assistant surgeon of the Sixty-Eighth Battalion Kings County' Militia in 1869, and served continuously thereafter in the militia and Canadian Army Medical Corps, of which he was at the time of his death surgeon colonel In 1874, he was elected to the House of Commons from Kings County, N S, and has served continuously, excepting during the years from 1883 to 1886 To Sir Frederick Borden's efforts were due in a large measure the efficient organization of the Canadian troops which was of so great assistance to Great Britain during the Boer War, in which his son, Lieut Harold L Borden, was killed in action

James Henry, M D., Orangeville, Ont , University of Toronto Ont., 1863, aged 73 a member and for several years vice president of the Ontario Medical Council, for more than half a century a practitioner of Dufferin County, surgeon in the Canadian militia and lieutenant colonel on the retired list of the thirty-sixth infantry, coroner for the counties of Peel Grey Dufferin and Wellington and division surgeon for the Canadian Pacific Railroad, died at his home, October 29, from cerebral hemorrhage

Carl Johann Luyties, M D, St Louis, Missouri Medical College St. Louis 1884, Hahnemann Medical College Philadelphia, 1885 aged 56 a Fellow of the American Medical Association a member of the visiting staff of the St Louis Childrens Hospital and St Louis City Hospital, a specialist on diseases of children professor of chemistry and later professor of diseases of children in the Homeopathic Medical College of Missouri St Louis, died at his home, December 23 from cerebral hemorrhage

Edward Marshall Buckingham, M D, Boston, Harvard Medical School 1874, aged 68, a Fellow of the American Medical Association and New England Pediatric Society instructor in diseases of children in his alma mater and for more than twenty years treasurer of the Massachusetts Medical Society, for many years secretary of the staff of the Boston City Hospital and visiting physician to the Children's Hospital, died at his home, December 23, from angina pectoris

James Wendell Reber, M D, Philadelphia, Beaumont Hospital Medical College St Louis 1889, aged 50, a Fellow of the American Medical Association, formerly assistant physician at the State Hospital for the Insane, Norristown, Pa , professor of ophthalmology in Temple University and the Philadelphia Policlinic, once president of the American Academy of Ophthalmology and Oto-Laryngology, died at his home in Germantown December 30 from pneumonia

Matthew Watson O'Brien, M D, Alexandria, Va , Medical College of Ohio Cincinnati, 1876, aged 61, a Fellow of the

American Medical Association, formerly vice president of the Medical Society of Northern Virginia, and president of the Southern Railway Surgeons' Association, local surgeon for the Southern, Chesapeake and Ohio, Washington and Old Dominion and Washington Southern railroads, died at his home, December 28

Frederick David Bentley, M D, Portage, Wis , Rush Medical College, 1886, aged 52, a Fellow of the American Medical Association, assistant superintendent of the Cook County Insane Hospital, Dunning, from 1889 to 1890, for several terms health officer of Portage, local surgeon to the Chicago, Milwaukee and St Paul System, who built and maintained the first hospital in Portage, died at his home, December 23

William H White, M D, Bloomfield , University of Pennsylvania, Philadelphia, 1860, aged 79, a Fellow of the American Medical Association, president of the Bloomfield Press Company and a member of the Bloomfield Board of Education, a veteran of the Civil War in which he served as surgeon of the Seventy-Ninth Pennsylvania Volunteer Infantry, died at his home, December 28, from pneumonia

Miah B Sullivan, M D, Dover, N H , New York University, New York, 1880, aged 59, a member of the New Hampshire Medical Society, and formerly president of the Strafford District and Dover medical societies, for many years a member of the surgical staff of the Wentworth Hospital once state senator, founder of the Dover *Evening Star,* died at his home December 26

Alexander H Saxton, M D, Baltimore, University of Maryland, Baltimore, 1863, aged 75, attending physician to the Baltimore General Dispensary and physician to St Mary's Industrial House of the Good Shepherd, for ten years vaccine physician and for eight years pension surgeon, state medical examiner for the Royal Arcanum, died at his home, December 24, from heart disease

William S McCormick, M D, Philadelphia, Medico-Chirurgical College of Philadelphia 1903, aged 40, formerly a Fellow of the American Medical Association, for five years a medical inspector for the board of health of Philadelphia, formerly assistant demonstrator of anatomy in his alma mater, died in the Methodist Hospital, Philadelphia, December 30, from diabetes

Peter Sebastian Ganz, M D, Louisville, Ky , University of Louisville, Ky , 1894, aged 55, a member of the Kentucky State Medical Association, and a director of the St Lawrence Home for Boys, for several years a member of the faculty of his alma mater and a member of the staff of Sts Mary and Elizabeth's Hospital, formerly a druggist, died at his home, December 23

James A Clyne, M D, Joliet, Ill , Albany (N Y) Medical College, 1886, aged 56, a Fellow of the American Medical Association, formerly president of the Will County Medical Society, local surgeon of the Chicago and Alton Railroad for twenty years, and in 1893 and 1894 health officer of Joliet, died at his home, November 8, from carcinoma of the throat

Julius Alexander Becker, M D, New York, New York University New York 1898, aged 41, a member of the Medical Society of the State of New York, professor of practical anatomy in the New York University and Bellevue Medical College, assistant surgeon to Bellevue Hospital and police surgeon, died at his home, December 25, from pneumonia

James Graham Wittenmyer, M D, Peebles, Ohio, Starling-Ohio Medical College, Columbus Ohio, 1913, aged 29, a member of the Ohio State Medical Association, lieutenant in the Medical Corps of the Ohio National Guard and assigned to duty with Field Hospital No 2, Columbus, died in the Base Hospital at Fort Bliss, Texas, December 9

Charles N Wyatt, M D, Easley, S C , Southern Medical College, Atlanta, Ga , 1887, aged 53, a Fellow of the American Medical Association, twice president of the Pickens County Medical Society , a trustee of the Medical College of South Carolina, local surgeon of the Southern Railroad, died at his home, December 27, from chronic nephritis

John R Borland, M D, Franklin, Pa , Philadelphia University of Medicine and Surgery, 1865, aged 88, a member of the Medical Society of the State of Pennsylvania, formerly professor of theory and practice of medicine and dean of the faculty of the Georgia Eclectic Medical College, Atlanta, died at his home, December 26

Ethelbert Fremont Geer, M D, St Paul, University of Vermont, Burlington, 1884, aged 58, a Fellow of the American Medical Association, formerly secretary of the Ramsey County Medical Society, for three years a member of the St Paul workhouse board, died at his home, December 24, from cerebral hemorrhage

Edmund Doe Spear, M D, Boston, Harvard Medical School, 1874, aged 64, formerly a Fellow of the American Medical Association, a member of the Massachusetts Medical Society and American Otological Society, a specialist on diseases of the nose and throat, died at his home, December 25, from pneumonia

George T Thomas, M D, Rogers, Texas, Missouri Medical College, St Louis, 1885, aged 61, a member of the State Medical Association of Texas, and once president of the Bell County Medical Society, died suddenly at Jonesboro, Texas, December 21, from cerebral hemorrhage

John Snyder, M D, Mecosta, Mich , Detroit College of Medicine and Surgery, 1886, aged 54, a Fellow of the American Medical Association, who was obliged to give up practice five years ago on account of disease of the spine, died at his home, December 11, from angina pectoris

Kenneth Charles Richman, M D, Philadelphia, Jefferson Medical College, 1911, aged 30 a specialist in laryngology and rhinology, a member of the staff of the Philadelphia General Hospital and Rush Hospital, died at his home, December 8, from heart disease

Joseph Huston McKee, M D, Carnegie Pa , Western Pennsylvania Medical College, Pittsburgh, 1891, aged 54, a Fellow of the American Medical Association, and president of the Carnegie Medical Association, died at his home, December 25, from pneumonia

E Lloyd Irvine, M D, San Francisco, University of Oregon, Portland 1905, aged 33, formerly a practitioner of Portland and a Fellow the American Medical Association, died in St Luke s Hospital, San Francisco, December 4, from lobar pneumonia

Benton F Tatum, M D, Stuart, Va , University of the South, Sewanee, Tenn , 1900, aged 45, a member of the Medical Society of Virginia, who underwent surgical operation recently, in Richmond, died at his home, December 29

Cummins Butterfield Jones, M D, Los Angeles, Miami Medical College, Cincinnati, 1873, aged 67, formerly superintendent of the Ohio Soldiers' and Sailors' Orphans Home, Xenia, died at his home, December 23, from heart disease

Charles C Dellenbaugh, M D, Portland, Mich , University of Buffalo N Y, 1859, aged 82, formerly a Fellow of the American Medical Association, for more than half a century a practitioner of Portland, died at his home, December 25

Frank Gamon, M D, Erie, Pa , Medico-Chirurgical College of Philadelphia, 1903, aged 36, a member of the Medical Society of the State of Pennsylvania, a specialist in anesthesia, died in Hamot Hospital, Erie, December 23

Joseph Dobson, M D, Fairfield, Conn , United States Medical College New York, 1880, aged 79, surgeon in the British army during the Boer War, died in Bridgeport Hospital, November 25 from chronic interstitial nephritis

Norman J Cranmer, M D, River Falls, Wis , Detroit Medical College, 1870, aged 80, for forty years a practitioner of Van Buren, Allegan and Missaukee counties Mich , died at the Hotel Gladstone, River Falls, December 7

William J Dillenback, M D, Brentwood, Md , George Washington University, Washington, D C 1888, aged 51 a member of the Medical Society of the District of Columbia died at his home, December 27 from diabetes

James W Fitzmaurice, M D, Chicago; Rush Medical College, 1889, aged 56, formerly a member of the Illinois State Medical Society, died at his home, December 29, from uremia

Effa A Osborn Norton, M D, Chicago, Curtis Physio Medical Institute, Indianapolis, 1896, died at her home, December 22, from diabetes

Lothar M Schwarz, M D, Chicago, Jenner Medical College 1897, aged 54, died at his home, December 21, from cirrhosis of the liver

John Capell, M D, Watson, Ark , Chattanooga (Tenn) Medical College, 1907, died in St Joseph's Hospital, Memphis, Tenn , November 21

Warner Lewis, M D, Wayland, Va , University of Maryland, Baltimore, 1867, a Confederate veteran, died at his home, December 10

Reuben Eiseman, M D, Latrobe, Pa , Jefferson Medical College, 1887, aged 55, died at his home, December 13

Eben Vernon, M D, Los Angeles, Atlanta (Ga) Medical College, 1859, aged 78, died at his home December 16

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

IRON CITRATE GREEN

Report of the Council on Pharmacy and Chemistry

H K Mulford Company and E R Squibb and Sons submitted to the Council ampules containing solutions of iron citrate green It thus became necessary to consider the eligibility of iron citrate green itself for admission to New and Nonofficial Remedies As the rules of the Council provide that nonessential modifications of official or nonproprietary preparations will not be recognized, the above named firms were asked to state what advantages if any, the so-called iron citrate green had over the official iron and ammonium citrate In reply the H K Mulford Company wrote that it had come to the conclusion that iron citrate green and ampules thereof would undoubtedly be considered by the Council as a nonessential modification of an official product, adding

> It seems to differ from the official ferric citrate so far as essentials go only in color but custom which is exceedingly hard to change in South America demands that this green variety of ampules be used in place of the official product

In reply to a similar letter of inquiry E R Squibb and Sons wrote

> Iron citrate green (iron and ammonium citrate green) differs from the U S P iron and ammonium citrate in that it contains less iron and more citric acid and more ammonium citrate than does the latter It is of course a modification of the official salt and is supplied to meet a real demand Its reaction is quite decidedly acid and our present stock contains Fe slightly below the U S P requirements for iron assaying 15 74 per cent instead of 16 per cent Fe The tests used to control its quality are those for the official product except as before indicated it is always acid instead of neutral as the U S P requires for that salt'

The smaller iron content (98 per cent of the U S P requirement) of the green variety referred to by E R Squibb and Sons is so small as to be negligible Further the low iron content as well as the acidity of the green salt would appear to be detriments rather than advantages Inasmuch as no evidence has been presented to show that iron citrate green is superior in any way to the well-known iron and ammonium citrate the Council held that iron citrate green, and with it the dosage forms was ineligible to N N R

The preceding report was submitted to the Mulford Company and to E R Squibb and Sons for comment before publication The former firm replied that in the present case it felt bound to supply the existing demand the latter replied that, to give the Council its support in this matter, the sale of iron citrate green and ampules thereof would be discontinued

MORE MISBRANDED NOSTRUMS

GOFF'S COUGH SYRUP' AND GOFF'S HERB BITTERS"

S B Goff & Sons Co of Camden N J were charged with shipping in interstate commerce a quantity of Goff's Cough Syrup and of Goff's Herb Bitters both of which were declared misbranded The 'Cough Syrup' was sold under the claim (made on the trade package) that it would prevent fatal membranous croup pneumonia and bronchitis, that it was a powerful restorative for the throat and lungs and was a remedy for pneumonia bronchitis, spitting of blood, whooping cough weak lungs' pleurisy and grippe The federal chemists reported that the stuff contained 8 per cent alcohol, about 55 per cent sugar, as well as some vegetable extractives and traces of iron, iodids antimony and alkaloids The government declared that the claims made for this preparation were false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity The Herb Bitters' were sold under the claim that Typhoid Fever, La Grippe, Malaria and Appendicitis cannot possibly exist in the system when Goff's Herb Bitters are taken regularly according to directions" The government chemist reported that the stuff was a water-alcohol solution of aloes, sugar and alkaline carbonate flavored with peppermint The claims quoted above were declared false and fraudulent and applied knowingly The company pleaded guilty and was fined $25 —[*Notice of Judgment No 4332*]

DANDER-OFF

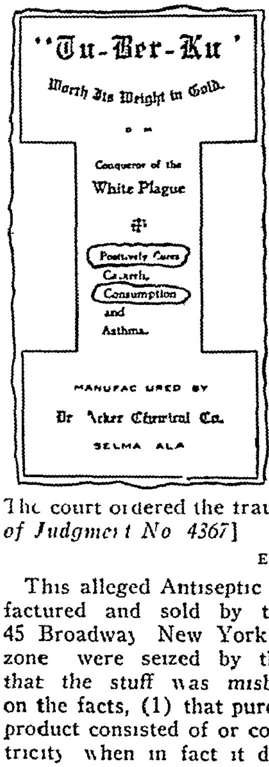
The C Hughel Co, Indianapolis, Ind, were charged with shipping in interstate commerce a quantity of Dander-Off which was misbranded The federal chemists reported that the preparation was an alkaline solution of borax and white arsenic colored with coal-tar dye It was claimed to be superior for all forms of dandruff and for all diseased and eczemic affections of the scalp and to be effective for restoring lifeless hair to good condition and causing the hair to grow more abundantly These and similar claims were declared by the government to be false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity The C Hughel Co pleaded guilty and was fined $50 and costs —[*Notice of Judgment No 4331*]

TU-BER-KU

The Dr A W Acker Chemical Co of Selma, Ala, shipped in interstate commerce 144 bottles of 'Tu-Ber-Ku" which the government declared were misbranded in violation of the Food and Drugs Act The preparation which admittedly contained 20 per cent alcohol was sold under such claims as

> Tuberculosis Can Be Cured Tu Ber Ku Triumphs
>
> It is a Blood Cleanser a Lung Builder a Flesh Maker a Health Restorer and an effective agency for fighting and curing Tuberculosis
>
> Has cured Consumption Catarrh Lagrippe Asthma and severe colds'

These and similar claims were declared by the government to be false, misleading and fraudulent The Dr Acker Chemical Company filed an answer to the libel claiming the product and the case was brought before the court and a jury After due deliberation the jury returned a verdict sustaining the government's charges The court ordered the fraudulent nostrum destroyed —[*Notice of Judgment No 4367*]



"Tu-Ber-Ku'
Worth Its Weight in Gold.
Conqueror of the
White Plague
Positively Cures
Catarrh,
Consumption
and
Asthma.
MANUFACTURED BY
Dr Acker Chemical Co.
SELMA ALA

ELECTROZONE

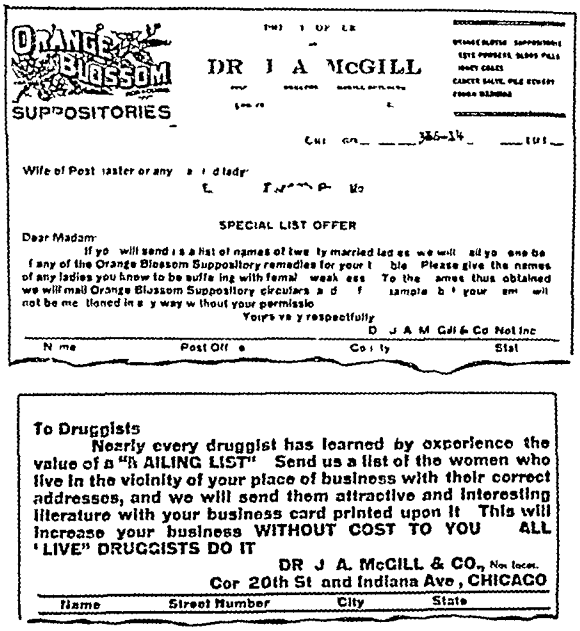
This alleged Antiseptic Germicide Disinfectant was manufactured and sold by the Chemical and Electrical Co, 45 Broadway New York Eighty-four bottles of Electrozone were seized by the government under the charge *that the stuff was misbranded* This charge was based on the facts, (1) that purchasers were led to believe that the product consisted of or contained ozone associated with electricity when in fact it did not contain ozone and was not associated with electricity, (2) in that the chemical formula indicated that the product was composed of certain chemicals of which in fact it was not so composed, (3) in that ozone was not formed together with nascent oxygen and peroxid of hydrogen when the hypochlorites were brought in contact with organic matter as was claimed on the label, (4) in that the stuff liberated no ozone, although the company claimed that when Electrozone was freely sprayed into an atmosphere containing carbonic acid gas, it neutralized this gas and filled the air with a fresh supply of oxygen Electrozone was recommended by its exploiters for piles, cholera infantum leukorrhea rheumatism, eczema, *sunburn*, diphtheria, 'falling hair," ear ache and various other conditio[illegible] These claims the government declared false and frad[illegible]ent and applied 'with a knowledge of their falsity' and had be[illegible] made *for the purpose of defrauding purchasers*' The

Chemical and Electrical Company appeared as claimant and having consented to the entry of a decree, with the understanding that it should apply only to certain of the therapeutic claims, the court declared that the stuff was "misbranded in so far as it relates to some of the therapeutic effects" made and declared the product condemned and forfeited and ordered that a judgment be entered against the claimant for the cost of the proceedings It was provided, however that after payment of the costs, the company might execute a bond of $500 and the Electrozone would be turned over to it on the condition that it should be relabeled under the supervision of the federal official —[*Notice of Judgment No 4355*]

ORANGE BLOSSOM FEMALE SUPPOSITORIES

John A McGill, Chicago, Illinois, has for years been selling a nostrum known as "Dr Jno A McGill Orange Blossom Female Suppositories" Some of the claims that have been made for this nostrum are

> 'A famous remedy for all female diseases'
>
> The famous Suppository is a Noble Remedy for the following diseases Inflammation, Congestion and Falling of the Womb, Anteversion, Retroversion and Prolapsus, Dropsy of the Womb Ulceration, Polypus Tumors Leucorrhoea, Profuse and Difficult Menstruation, Ovarian Tumors Fibroid Tumors, Inflammation and Congestion of the Ovaries, Cancers in their Earlier States '



ORANGE BLOSSOM SUPPOSITORIES

DR J A McGILL

Chicago ___ 3-6-14 ___ 191_

Wife of Postmaster or any married lady

SPECIAL LIST OFFER

Dear Madam

If you will send us a list of names of twenty married ladies we will mail you one box of any of the Orange Blossom Suppository remedies for your trouble Please give the names of any ladies you know to be suffering with female weakness To the names thus obtained we will mail Orange Blossom Suppository circulars and free sample but your name will not be mentioned in any way without your permission

Yours very respectfully

Dr J A McGill & Co Not Inc

Name Post Office County State

To Druggists

Nearly every druggist has learned by experience the value of a "MAILING LIST" Send us a list of the women who live in the vicinity of your place of business with their correct addresses, and we will send them attractive and interesting literature with your business card printed upon it This will increase your business WITHOUT COST TO YOU ALL 'LIVE" DRUGGISTS DO IT

DR J A. McGILL & CO., Not Incor.
Cor 20th St and Indiana Ave , CHICAGO

Name Street Number City State

Two methods used by McGill to obtain a sucker list Letters sent to the wives of village postmasters and letters sent to druggists asking for the names of married ladies who are suffering from "female weakness'

The government chemists reported that analysis of the 'Orange Blossom Female Suppositories" showed that they contained "free boric acid, aluminum salt, sulphate, potassium salt sodium salt starch and petrolatum [vaseline]" As such a mixture will not cure "Cancers in their Earlier States," "Falling of the Womb" or the various other conditions claimed by John A McGill, the government declared these statements to be false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity McGill pleaded guilty and was fined $50 and costs —[*Notice of Judgment No 4360*]

DR SIMPSON'S VEGETABLE COMPOUND

"Dr Simpson's Vegetable Compound was put on the market by the "Dr A B Simpson Co" of Richmond, Ind, which was merely a trade name under which Thomas C Davis and Eva J Cole did business In spite of this, the cartons of the nostrum bore the following statement

> The undersigned, citizens of Richmond take pleasure in saying that more acquainted with Dr A B Simpson and for the sake of suffering humanity we cheerfully recommend him and his treatment Wm H Schlater Clerk Circuit Court S S Strattan, Treasurer Wayne Co T W Bennett Mayor of Richmond Jos P Iliff Chief of Police Thos C Davis Agt U S Express Co P C Graff Agt Adams Express Co"

The preparation was sold as a specific for erysipelas, all diseases of the skin, inflammatory rheumatism scald head, salt rheum and tetter The chemists of the Department of Agriculture reported that the stuff was essentially an alcohol-water solution of potassium iodid with a small amount of vegetable extractive, in which podophyllum, licorice and gentian were indicated The therapeutic claims were declared false and fraudulent while, in addition, misbranding was charged because the amount of alcohol present was not truthfully stated and because further a solution of potassium iodid cannot properly be called a "Vegetable Compound' Eva J Cole pleaded guilty to a part of the indictment and was fined $25 and costs The indictment was *nolle prossed* as to the defendant Davis —[*Notice of Judgment No 4363*]

WELLER'S STONE ROOT AND GIN

This preparation was put on the market by W L Weller & Sons Louisville, Ky The stuff, which admittedly contained 37½ per cent of alcohol, was advertised as "An Excellent Preparation for Kidney, Bladder and All Urinary Troubles, Also an Efficient Relief for Nervous Debility and Dyspepsia As a Tonic It Has No Equal" These and similar claims were naturally declared by the federal authorities to be false and fraudulent and applied knowingly and in reckless and wanton disregard of their truth or falsity W L Weller & Sons having admitted the facts and consented to a decree, the court ordered that the stuff should be relabeled under the supervision of the United States food and drug inspectors and restored to the company, after the costs of the proceedings had been paid and a bond in the sum of $100 executed —[*Notice of Judgment No 1297*]

Correspondence

Rural Obstetrics

To the Editor —In a discussion on this subject abstracted in The Journal Dec 9 1916 p 1785, two women physicians took occasion to belittle the ability of the rural practitioner of this branch of the practice of medicine

This is no new subject The 'country doctor' is looked down on professionally by many of his colleagues who happen to reside in larger communities

It is hard to see why this should be In the article referred to the statement is made that "these men are sent out from our medical colleges and schools with nothing but a smattering of knowledge of the mechanics of childbirth" So far as medical college teaching with its accompanying hospital service is concerned, it is to be remembered that the practitioners in rural communities did not learn their profession there That time has long passed We country doctors, as far as my knowledge extends are originally from the same schools as our city colleagues If one takes the trouble to look into the matter he (or she) will find that as large a proportion of these doctors come from first-class schools as the physicians living in larger cities

With respect to facilities for keeping up to date after graduation, of course the resident of the larger city has much greater opportunities He can more easily attend the lectures and clinics of specialists, and see large numbers of cases But it will be noticed by one who visits the postgraduate schools that their attendance is not made up of physicians living in the city in which the school may be located On the other hand these valuable institutions are attended principally by those who would be classified as "country doctors' many hundreds of whom have left lucrative and otherwise successful practices and traveled long distances, frequently half way across the continent, to obtain such advantages

Since we do not have medical libraries located near by, our private ones are well stocked, and the books are not for ornament—they are used The mail brings us in constant touch with the same information which is accessible to our city brothers (and sisters) Our journals are not thrown unopened in a pile behind the door or on a shelf to be finally discarded without being unwrapped They are used to keep us in touch with what is going on in the centers of teaching and experimentation

In the matter of personal experience after his graduation, the country doctor is in a position in which he must keep up with the profession He has not the specialists in every line or easily accessible large hospitals to which he may turn over his cases when they are more or less puzzling Most country practitioners are not so happily located, for instance, that they can call an ambulance and shift the responsibility of a septic obstetric patient to the shoulders of a large hospital, and so have their own mortality rates kept down

On the contrary, the man practicing in the country must bear his own burdens, and he is in a position to be personally blamed (or sometimes praised) for his results With this in mind, the practitioner who has the moral and physical backbone to practice away from the larger cities is always doing his best for his patients even to the end, and is always trying to extend his limitations

The only country doctors with whose personalities and results I am acquainted are western ones, and I am not ashamed to count myself one of them

The county in which I reside has an area of over 5,600 square miles, and a population of a little over 7,500 There are usually eight or nine physicians residing in the county The result is that we often attend obstetric patients at distances of 30 or 40 miles from our residences, thanks to the automobile, though many of our roads are in the mountains

Of course there are disadvantages for the patients and discomforts for the doctors in this sort of practice, but some one must do it We realize that under such circumstances the daily visit is impossible On the other hand, we know that such daily visits do little to prevent or limit infections If these occur, whether in city or in country, they are almost invariably caused at the time of labor The consequence is that if proper asepsis is carried out at the time of delivery, there will be little more mortality or morbidity than if the woman lived in a large city

Since we have been in the registration area, there have been in this county 1,140 full-term births, about 1,100 of them reported by physicians In this number there have been four deaths directly attributable to labor One of these deaths was due to puerperal sepsis one to pulmonary embolism and two to eclampsia Neither of the eclampsia patients was under the care of a physician until after the onset of serious convulsions A physician had not been engaged to attend them One of them was over 30 miles from a physician, and the other about 15 miles away

Careful examination of death certificates filed during the registration period does not show the deaths of other mothers from 'typhoid fever,' "acute tuberculosis," "malaria" or any of those conditions which are sometimes made use of, intentionally or otherwise, to cover deaths due to puerperal infection These mothers were followed up, through the death certificates, for a period of three months after labor, and none of them died during that time from any cause whatever

Of the physicians attending these 1,100 confinements five have practiced in this county for varying lengths of time during the registration period, while five have resided here during the whole time, so that to a greater or less extent the 1 100 labors were attended by ten different "country doctors '

Of course I have no means of comparing our local practitioners with those of other rural communities but I see no reason to believe that they are not representative country doctors, at least as regards this section of the United States

With such statistics at hand I certainly think I am justified in making protest against such belittling of the obstetric results of rural practitioners in general I cannot speak for or against those of the eastern country districts, but only so far as refers to the section in which I happen to reside

Finally, we do not take kindly to criticism from such sources as those from which the discussion referred to seems to have originated On looking up the pedigrees' of the ladies in the fourth edition of the American Medical Directory copyrighted in 1914 I find that one of the critics was not yet in practice, at least in the United States or Canada—less than three years ago The other critic seems, according to the same authority, to have graduated from a medical college located in a "city" of about 10 000 population At the time of publication of the directory of 1914, she was still located in the same center of learning

Maurice A Walker, M D, Dillon, Mont

"Another 'Contemptuous Verdict'"

To the Editor —In your issue of December 16 you refer to a certain, or rather, uncertain 'dealer in rugs" as having been called a swindler by the *Tribune* Why this better part of valor" in discreetly suppressing the details? The *Tribune* evidently had courage enough to expose a fraud and take a chance Full publicity of such cases is for the good and protection of the community and a further deterrent to evil In some countries the convicted party must publish the decision of the court in a number of papers Now, if it was a libel suit The Journal feared, it could have limited itself to a citation of the case from the records giving the name of plaintiff and defendant as it does in its medicolegal column No accusation could possibly lie on the publication of a finding of a court, and your readers would know, as they really have a right to know, who the dealer was and where we were to find his "large and commodious pitfall '

P H F

[Comment —Our correspondent submitted with this letter what he doubtless considered an appropriate caption "Editorial Discretion and 'Contemptuous Verdicts' ' The implication that The Journal hesitates to give facts for fear of incurring a libel suit is really humorous There was just one reason that the name and address of the 'dealer in rugs" was not given in the editorial in question it had nothing to do with the case The Journal's editorial was simply a comment on the principle involved in "contemptuous verdicts" That was all It was neither conceived nor written with the idea of protecting The Journal readers from Maine to California and from Oregon to Florida from the alleged "large and commodious pitfall" located in a retail establishment on Fifth Avenue, New York City As "P H F" lives in New York City, an investment of one cent in the New York *Tribune* for Dec 5, 1916 will give him full information about the case —Ed]

TESTAMENTARY CAPACITY

To the Editor —Please tell me what is the usual test given by alienists to persons claimed to be mentally unsound with reference to their capability to transact business and make their wills There is to come up in the near future the case of a man who made his will over four years ago in favor of his wife and then afterward of his daughter The man worked on a farm all his life He was of more than ordinary intelligence compared with the older farmers in the locality and accumulated a small fortune by hard labor and thrift He helped all the other children to own farms of their own After an illness lasting five weeks caused by overheating on a horseback ride, he died at the age of 78 years During this illness he was delirious at times, there was albumin in the urine, etc All the business men with whom I have talked regarding his soundness of mind state they had never discovered any mental unsoundness or a condition different from that of any other normal man with whom they had transacted business I will thank you for any information you may send me bearing on this case especially what points the contestants are likely to introduce as evidence in their attempt to break the will

R S D

Answer —The laws relating to what constitutes capacity to make a valid will vary so much in different states that there can be no uniform rule as to how the mental element of that capacity can be tested by an alienist It follows, therefore, that it is never the function of an alienist to pronounce on this capacity This is the duty of the court before which the validity of a will is contested The alienist will testify only as to the condition of mind of the testator In some countries proof of the slightest degree of mental alienation at the time of the execution of a testament will suffice to invalidate it At the other extreme we find the conservative laws on the subject which prevail where the English common law is taken as the basis of legislation Under the latter systems it is difficult to upset a will on the ground of mental incapacity

Were an alienist to permit himself to give an opinion as to the testamentary capacity of a testator he would have either to give a different opinion in different countries which would be to assume the right of interpreting law, or to give the same opinion in all countries, which would constitute an attempt on the part of the alienist to legislate In the one case he would be usurping the functions of the court, in the other he would be trespassing on the domain of the legislator Nevertheless, an expert testifying in such a case will usually be familiar with the local law on testamentary capacity He will therefore direct his attention more particularly to those elements of the mentality of the testator which, under the local law are relevant to the latter's testamentary capacity

What these would be in the particular case you set out we are unable to appreciate In general, however, the points of importance in a man of the age of 74 and in the condition which you have described would be his memory for recent events, his knowledge of the nature and extent of the property of which he was purporting to dispose and of his relations thereto, the extent to which persons who in the ordinary event, might be expected to benefit by his will, and especially his natural heirs and successors would be present to his mind in their proper atmosphere at the time he executed the document, and lastly his knowledge of the nature and consequences of the act which he was performing An expert may testify in such a case on the results of an examination actually made by himself or he may as an opinion witness enlighten the court by interpreting the effect of the evidence of other persons, or by answers to hypothetic questions We gather from your letter that the latter procedure is the one likely to be adopted in the case you cite

There is one point which is not expressly raised by our correspondent, but which should be borne in mind When there is evidence brought forward tending to show that the testator, though not of unsound mind to such a degree as to incapacitate him from making a will, was nevertheless not of entirely sound mind in the ordinary sense of the expression, this kind of evidence is often relied on and acted on by the court, not to invalidate the will on the ground of unsound mind but to supplement any other evidence there may be in support of an attempt to upset the will on the ground of undue influence

MOUTH WASH

To the Editor —In the *Journal of Infectious Diseases* 1906 3 793 there was an article by Dr A B Wadsworth now director of the Division of Laboratories and Research of the New York State Department of Health giving a detailed description of a mouth wash Please publish it in Queries and Minor Notes H D T

RUPTURE OF THE ACHILLES TENDON

To the Editor —Please let me know what the prognosis is in a case of complete rupture of the Achilles tendon at about the junction of the tendon and the muscles Please do not publish my name B A R

ANSWER—The prognosis in complete rupture of the Achilles tendon is good, provided operation is performed and the tendon properly sutured If the rupture is a subcutaneous one and there are no contraindications, the operation should be done at once If the rupture is compound, the question of the time to operate will depend on the condition of the wound as to the presence or absence of infection If the wound is not infected, immediate operation should be done In the presence of severe infection, operation should be postponed until the infection has been cleared up

SPIROCHAETA PALLIDA OR TREPONEMA PALLIDUM?

In Reply to Dr Stiles

WILLIAM ALLEN PUSEY, A M, M D
CHICAGO

In reply to Dr Stiles argument, I would make two points

First, the genus *Treponema,* and specifically the organism of syphilis, are not so sharply distinguished from the *Spirochaeta* that the genus *Treponema* can be held to be finally established without any reasonable doubt as to the validity of the genus, and, this being the case, the argument for the name *Treponema pallidum* is based on uncertain ground when it rests on reasons of classification alone

Second, an overwhelming preponderance of authoritative usage has fixed the name *Spirochaeta pallida* in scientific literature as the name for the organism of syphilis Dr Stiles assumes that the distinctions between the *Spirochaetae* and the *Treponemata* are clear and definite and that the establishment of the genus *Treponema* as distinguished from the *Spirochaeta* is final The whole classification argument is based on this assumption

I do not presume to offer my opinion on a question of zoological nomenclature against that of Dr Stiles, but I may without presumption point out that there is a difference of opinion among microbiologists as to the classification of the organism of syphilis Its place is not definitely and with unanimity settled outside the genus *Spirochaeta* Dr Stiles himself very clearly points out that there are, as regards this point, two groups among zoologists, the 'lumpers' and the "splitters" The very fact of the existence of the two groups is the best evidence of the differences of opinion as to this matter of classification

It is not difficult for me, without being conversant with the literature of protozoology, to find eminent authorities who differ from the International Commission on Zoological Nomenclature about the name of the organism of syphilis One of these is no less a person than Metchnikoff, Chef de Service de Microbiologie de l'Institut Pasteur, not a physician who, in his exhaustive article on the microbiology of syphilis in the "British System of Syphilis," says, 'I consider that the time is still premature to make any classification of spirillar micro-organisms"

Again, Dr Novy, professor of bacteriology in the University of Michigan, who has perhaps done more work on the spirochetes and allied forms than any other American expert, indicates in a communication to me, which I quoted in my previous article that in his opinion the separation of the organism of syphilis from the spirochetes is not established beyond question when he says "The term *Spirochaeta* has come into such general use that it hardly seems worth while to make a change unless the difference is absolutely conclusive"

Further, Dr Calkins, professor of protozoology in Columbia University, not a physician in commenting in his Protozoology' on the uncertainties of classification and the difficulties in determining the characteristics of these organisms, has this to say

> *Spirochaeta* thus characterized as an organism with flexible spirally twisted body with a laterally placed undulating membrane would seem to be definitely distinguished but unfortunately, the problem is not so simple for we have to do with exquisitely minute things which offer extreme difficulties in technical treatment Statements as to structure and activities of certain species even though made by equally eminent authorities, are frequently directly contradictory
>
> Observations are too incomplete and too often contradictory to justify a safe grouping at the present time and in making groups of spirochetes a given species will be placed in one division or another according to the discretion of the present author in following one or another authority With this preliminary caution the following table of the different kinds of spirochetes classified according to the presence or absence of so-called flagella and undulating membrane is based

He then classifies these organisms as follows

A Type genus *Spirocheta* With undulating membrane, without flagella

B Genus *Treponema* Without undulating membrane, with flagella

C Undetermined forms referred to genera *Spirocheta* and *Spirillum*

A great difference of opinion as to the classification of these organisms is seen when one compares the species in genus *Treponema* as given by Calkins in his "Protozoology" with the species in the same genus as given by Fantham in The Animal Parasites of Man" by Fantham Stephens and Theobald Calkins includes under the genus *Treponema* *Tr pallidum* *Tr pertenue* *Tr anserinum*, *Tr gallinarum* *Tr theileri* *Tr muris* Fantham gives only *Tr pallidum* and *Tr pertenue* but indicates that there are other members of the genus The interesting fact comparing the two classifications, is that three species of the six which Calkins classifies as *Treponemata* Fantham classifies and describes as *Spirochaetae* The *Treponema gallinarum* of Calkins is the *Spirochaeta gallinarum* of Fantham The *Treponema anserinum* of Calkins is the *Spirochaeta anserinum* of Fantham The *Treponema muris* of Calkins is the *Spirochaeta muris* of Fantham

Bosanquet in his work Spirochetes" has the following to say concerning classification

> It has already been pointed out that the position of the spirochaetes in nature—whether they are to be regarded as protozoa or bacteria—is doubtful Their relations as a group are almost equally undecided
>
> Certain peculiarities observed in the *Sp pallida* led Schaudinn to put it in a distinct genus called *Treponema* The characteristics of this genus were the round shape of the body in section as opposed to the flattened shape of the spirochaetes the fixity of the curls exhibited by the organism the absence of an undulating membrane and the presence of terminal filaments
>
> Examination of the qualities on which this distinction is founded does not tend to strengthen a belief in its validity The round shape of the organism in section may be admitted but the ribbon like shape of the other small spirochaetes is not very clearly established The existence of an undulating membrane is doubtful even in the larger spirochaetes and still more problematical in the smaller group Terminal filaments may be found in other species besides *Sp pallida* and finally the even curls presented by this spirochaete may at times be absent as is admitted even by Schaudinn himself Norris Pappenheimer and Flournoy point out that the *Sp obermeieri* exhibits all the characteristics assigned to a treponema

The uncertainty of the taxonomic place of these organisms is quickly seen whenever a comparison is made of the views of different authors concerning them Schaudinn, as already shown, made as a distinguishing characteristic which separated the spirochetes from the treponemes, the presence of an undulating membrane in the spirochete, and the absence of an undulating membrane in the treponeme Yet Fantham says, in reference to this point, 'In some forms there is a membrane or crista present, which in the past was compared with the undulating membrane of a trypanosome, but the membrane of a spirochaete does not undulate" There is even uncertainty about the very type species of the genus *Spirochaeta* the *Spirochaeta plicatilis* of Ehrenberg discovered in 1838, for Zuelzer, as quoted by Fantham, says that the *Spirochaeta plicatilis* does not possess a membrane Again, Blanchard, according to Fantham, finds a slight membrane in the *Treponema pertenue* Here, then, we have this situation, Schaudinn establishes an undulating membrane as a critical characteristic of the *Spirochaeta* Fantham says that the membrane does not undulate According to Zuelzer's observation, the very type species of the *Spirochaeta* does not possess a membrane, and Blanchard finds a membrane in one of the species of the genus *Treponema* which has been separated from the genus *Spirochaeta* partly on the ground that its members do not possess a membrane

I think these few quotations will indicate the difficulties and the lack of unanimity in the taxonomy of this subject, and the weakness that must attach to any argument which would insist on naming the organism of syphilis on taxonomic grounds alone But even if there were not this utter uncertainty among authors now as to the classification of these organisms, experience indicates that increase in knowledge might entirely upset the classification in a short time As knowledge increases, "splitters" are quite as likely to be forced to 'lump" as "lumpers" are to "split" There is no inherent scientific virtue pertaining to either attitude It is not hard to cite experiences to illustrate this fact in the domain of microbiology Twenty-five years ago so good an authority as Prof William H Welch gave us the *Staphylococcus epidermidis-albus* as a species of staphylococcus It has long since been lumped with the *staphylococcus albus* A good recent illustration of the uncertainty of distinctions between micro organisms is the work of E C Rosenow who has shown by his researches that many cocci thought to be distinct and pathogenic varieties are probably one species of streptococcus presenting varying characteristics under different conditions There is even some uncertainty about the morphology of the organism of syphilis According to Bosanquet, Bertarelli and Volpino, Schereschewsky, Sobernheim and Tamasoli describe intermediate or irregular forms of *Spirochaeta pallida* Bosanquet says, *Spirochaeta* pallida is noted for the regularity of its curls and is indeed identified by this means, yet Schaudinn observed that almost straight forms might occur, " He adds, 'These observations are sufficient to indicate that considerable doubt must be felt as to the constancy of form among the small spirochaetes, "

In the face of such differences as shown above, and the confessedly meager and uncertain knowledge of the facts on which the classification of the spirochetes and allied organisms must be made, I believe the outsider may plead even against the testimony of so authoritative a body as the International Commission on Zoological Nomenclature, that the genus *Treponema* is not so firmly fixed that, on the grounds of classification alone the name Treponema can be insisted on for any given species in the genus regardless of other considerations

There are one or two collateral points in Dr Stiles article concerning which I should like to say a word His involving allegiance to the findings of the Commission on Nomenclature as a matter of ethics seems to me not apposite, and, if I understand the application which he makes of it, it must, I believe have been due to oversight Ethics scientific ethics included, concern matters of right and wrong and I am sure Dr Stiles does not believe that any scientific commission however important, is so august that failure to accept its findings is wrong That would be medieval worship of authority

He also refers to the confusion which is liable to occur from the use of *Spirochaeta* without qualification instead of the specific name, *Spirochaeta pallida* I believe there is little danger of confusion as to the meaning in an article on syphilis if the unqualified word spirochete should be used after *Spirochaeta pallida* had first been used And I certainly se no reason why there should be more confusion from the use of *Spirochaeta* alone than that of *Treponema* alone There are already several treponemes, and the unqualified word *Treponema* is certainly not less likely to lead to confusion than the more familiar word *Spirochaeta* without qualification

A word as to Dr Stiles' remarks regarding the backwardness of physicians and their failure to appreciate the difficulties of this subject as pure zoologists do So far as the specific instance which we are now considering is concerned, I do not think that it can be maintained that the pure zoologists stand as a unanimous group while the physician zoologists are chiefly responsible for the other group In looking up the position of authorities on this subject I took the first that came to hand They were Novy, Metchnikoff, Calkins, Fantham and Bosanquet Two of these five are not physicians (Calkins and Metchnikoff), and the other three, while physicians, are specialists in this field who have done original work of the highest class and I have no doubt could claim equal appreciation with the purest systematists of all of the difficulties of classification and nomenclature The physician zoologists are not responsible for the confusion, pure zoologists are equally uncertain The confusion lies in the uncertainty of the criteria on which the classification rest

But regardless of classification, my argument in favor of *Spirochaeta pallida* is based on the fact that *Spirochaeta pallida* is established by authoratative and greatly preponderating usage The argument would be just as strong for *Treponema pallidum* if usage were in its favor Dr Stiles indicates that there is some doubt as to what is meant by best usage as regards a word or linguistic form, and says, "Best usage from the point of view of the splitters is that usage which comes closest to expressing a natural classification of the organism'—in other words comes closest to expressing their views I venture to insist that such is not the meaning of the words "best usage or "good usage" as they are used in this connection, but, on the contrary, that they refer solely to precedent—the use by recognized authorities of any particular word in question Good use is a technical phrase which as such will be found in books dealing with linguistic forms It is an accepted principle that the criterion of the standing of words is such usage—not what you, or I, or any present body of men think should be the word to describe a thing, but what the word to describe it is, as shown by good precedent

As Barrett Wendell says in his work on English composition

> In English as in every other language the final test of what words we may use is inevitably the usage of those who speak and write it the test of what words we should use is the usage of those who speak and write it best in other words good use
>
> Common consent general practice is what makes the alphabet signify anything In this fact lies the hopelessness of the efforts now and then made by dogmatists not possessed of despotic authority to reform spelling [With equal truth we might substitute nomenclature here for spelling —W A P] The question in a given instance is not what ought to be the case but what is And to the state of things which enables us to decide in spelling as in other fashions what the case is at any given moment we give for convenience sake, the name Good Use.
>
> Dictionaries and grammars [or commissions on nomenclature —W A P] to be sure may codify what exists at any given moment Regarded as codes they are invaluable but at best they are codes of common law, not legislative enactments The only sanction behind them is that of practice of usage

Thus, usage, in the technical sense of good precedent establishes proper linguistic forms, and I would point out again that usage both in quantity and quality is overwhelmingly in favor of *Spirochaeta pallida* That point was brought out in my previous article Let me repeat here a few of the names of individuals to illustrate the quality of usage in favor of *Spirochaeta pallida*

Metchnikoff, who discovered the inoculability of syphilis in apes, and by this discovery made possible the present revolution in our knowledge of syphilis used *Spirochaeta pallida* Hoffmann, who was the codiscoverer of *Spirochaeta pallida* with Schaudinn, and whose name was never separated from Schaudinn's in giving credit for the discovery until after Schaudinn's death, uses *Spirochaeta pallida* Neisser, who with Wassermann and Bruck developed the serum complement reaction for syphilis and until his recent death was our greatest authority on clinical and experimental syphilis, used *Spirochaeta pallida* Uhlenhuth, whose researches in the chemotherapy of syphilis opened the way for Ehrlich and whose work Atlas der Experimental Kaninchen Syphilis' written in collaboration with Mulzer, is the authoritative book on experimental syphilis uses *Spirochaeta pallida* Ehrlich used *Spirochaeta pallida* Noguchi, the only other man whose work in syphilis entitles him to mention in the class with these men uses *Spirochaeta pallida* as a rule, but *Treponema pallidum* occasionally

These men of course are not a miscellaneous collection They, with Schaudinn who died within a year after the discovery of the *Spirochaeta pallida* are the men whose discoveries have made modern syphilis, and they and their followers have written *Spirochaeta pallida* into the literature of syphilis in such a way that it cannot be erased In the attempt to substitute *Treponema pallidum* the most that can be gained by the advocates of it is the use of both names for the organism Splitters and purists may use *Treponema pallidum* It is not beyond the possibilities that in time the taxonomic grounds for its use may be swept from under them and that they may be forced back to the use of *Spirochaeta pallida* But whatever they may do the universal use of *Spirochaeta pallida* in German, its overwhelmingly preponderant use in English, and its preponderant use in French mean that *Spirochaeta pallida* will continue to be the generally used name for the organism of syphilis For the sake of unanimity and clearness the use of two names for the organism should be avoided if possible Certainly this should not be brought about simply in the interest of a system of classification, which as respects the organism in question here, is based on characteristics whose finality is not certain

Liability of Father for Services for Daughter Away from Home

(Wallace vs Cox et al (Tenn) 188 S W R 611)

The Supreme Court of Tennessee affirms a judgment holding that the plaintiff was entitled to recover from defendant Cox as on an implied contract for a surgical operation and attendance on a 17 year old daughter of said defendant This daughter and an older one were in a nearby city earning their own living, when this one became ill and the plaintiff was called in by the matron of the Y W C A building where they were boarding After prescribing for the daughter for a time, the plaintiff decided that an operation was necessary to remove an ovarian tumor He had stated that the operation would be a slight one, and, when the elder daughter telephoned to their father that an operation was advised, and he inquired whether an incision would have to be made, she said that it would not, that the operation would be a slight one, and he replied "Well, then if it must be done, it must be done ' The elder daughter testified that the plaintiff did not ask her to telephone to her father, and that she did not inform him that she had done so for several days after the operation The plaintiff testified that in performing the services he looked to the father for compensation The father testified that he failed to hear the name of the surgeon over the telephone, that had he been informed that an incision was required, he would have gone to the city and had the operation performed by another surgeon with whom he was personally acquainted, and that he was not asked to and did not promise to pay for the operation The operation was successful Bills were sent to the father, who paid no attention to them and suit was brought The circuit judge, sitting without the intervention of a jury, held that the father was not liable The court of civil appeals divided on the question, the majority holding that the plaintiff was entitled to recover as on an implied contract, which latter is the judgment here affirmed The supreme court says that the liability of a father for necessary medical attention given a child who has not remained as a member of his immediate family is a question on which the authorities are at least in apparent conflict Cases fairly supporting either of the opposing rulings of the lower courts may be found, but a number of those holding with the judgment of the circuit court take color from English cases which proceed on the principle that a father is under only a moral obligation to support his child The obligation of the parent to support his child at common law was not well defined but in Tennessee it has been held more nearly in accord with the natural sense of justice that the obligation is not merely moral, but legal and enforceable as a legal common-law duty It therefore follows that if the parent neglect that duty any other person who supplies such necessary attention to the child is deemed ordinarily, to have conferred a benefit on the delinquent parent, for which the law raises an implied promise to pay on the part of the parent In this case the father did not successfully prove any emancipation of the daughter conferring on her the right to her earnings and terminating his duty to support her Her effort to earn her own support was praiseworthy and tended to lift a burden that rested on the father, and the courts should be slow to permit the fact to become a shield for his protection at least where a full emancipation was not shown The restoration of the daughter

He then classifies these organisms as follows

A Type genus *Spirocheta* With undulating membrane, without flagella

B Genus *Treponema* Without undulating membrane, with flagella

C Undetermined forms referred to genera *Spirocheta* and *Spirillum*

A great difference of opinion as to the classification of these organisms is seen when one compares the species in genus *Treponema* as given by Calkins in his Protozoology" with the species in the same genus as given by Fantham in 'The Animal Parasites of Man" by Fantham Stephens and Theobald Calkins includes under the genus *Treponema Tr pallidum Tr pertenue Tr anserinum Tr gallinarum Tr theileri Tr muris* Fantham gives only *Tr pallidum* and *Tr pertenue* but indicates that there are other members of the genus The interesting fact comparing the two classifications, is that three species of the six which Calkins classifies as *Treponemata* Fantham classifies and describes as *Spirochaetae* The *Treponema gallinarum* of Calkins is the *Spirochaeta gallinarum* of Fantham The *Treponema anserinum* of Calkins is the *Spirochaeta anserinum* of Fantham The *Treponema muris* of Calkins is the *Spirochaeta muris* of Fantham

Bosanquet in his work Spirochetes" has the following to say concerning classification

> It has already been pointed out that the position of the spirochaetes in nature—whether they are to be regarded as protozoa or bacteria—is doubtful Their relations as a group are almost equally undecided
>
> Certain peculiarities observed in the *Sp pallida* led Schaudinn to put it in a distinct genus called *Treponema* The characteristics of this genus were the round shape of the body in section as opposed to the flattened shape of the spirochaetes the fixity of the curls exhibited by the organism the absence of an undulating membrane and the presence of terminal filaments
>
> Examination of the qualities on which this distinction is founded does not tend to strengthen a belief in its validity The round shape of the organism in section may be admitted but the ribbon like shape of the other small spirochaetes is not very clearly established The existence of an undulating membrane is doubtful even in the larger spirochaetes and still more problematical in the smaller group Terminal filaments may be found in other species besides *Sp pallida* and finally the even curls presented by this spirochaete may at times be absent as is admitted even by Schaudinn himself Norris Pappenheimer and Flournoy point out that the *Sp obermeieri* exhibits all the characteristics assigned to a treponema

The uncertainty of the taxonomic place of these organisms is quickly seen whenever a comparison is made of the views of different authors concerning them Schaudinn as already shown, made as a distinguishing characteristic which separated the spirochetes from the treponemes, the presence of an undulating membrane in the spirochete and the absence of an undulating membrane in the treponeme Yet Fantham says, in reference to this point, 'In some forms there is a membrane or crista present, which in the past was compared with the undulating membrane of a trypanosome but the membrane of a spirochaete does not undulate" There is even uncertainty about the very type species of the genus *Spirochaeta* the *Spirochaeta plicatilis* of Ehrenberg discovered in 1838, for Zuelzer, as quoted by Fantham, says that the *Spirochaeta plicatilis* does not possess a membrane Again, Blanchard, according to Fantham, finds a slight membrane in the *Treponema pertenue* Here, then, we have this situation, Schaudinn establishes an undulating membrane as a critical characteristic of the *Spirochaeta* Fantham says that the membrane does not undulate According to Zuelzer's observation, the very type species of the *Spirochaeta* does not possess a membrane, and Blanchard finds a membrane in one of the species of the genus *Treponema* which has been separated from the genus *Spirochaeta* partly on the ground that its members do not possess a membrane

I think these few quotations will indicate the difficulties and the lack of unanimity in the taxonomy of this subject, and the weakness that must attach to any argument which would insist on naming the organism of syphilis on taxonomic grounds alone But even if there were not this utter uncertainty among authors now as to the classification of these organisms, experience indicates that increase in knowledge might entirely upset the classification in a short time As knowledge increases, 'splitters" are quite as likely to be forced to "lump" as 'lumpers" are to "split" There is no inherent scientific virtue pertaining to either attitude It is not hard to cite experiences to illustrate this fact in the domain of microbiology Twenty-five years ago so good an authority as Prof William H Welch gave us the *Staphylococcus epidermidis-albus* as a species of staphylococcus It has long since been lumped with the *staphylococcus albus* A good recent illustration of the uncertainty of distinctions between micro-organisms is the work of E C Rosenow, who has shown by his researches that many cocci thought to be distinct and pathogenic varieties are probably one species of streptococcus presenting varying characteristics under different conditions There is even some uncertainty about the morphology of the organism of syphilis According to Bosanquet, Bertarelli and Volpino, Scherescherwsky Sobernheim and Tamasoli describe intermediate or irregular forms of *Spirochaeta pallida* Bosanquet says, *Spirochaeta* pallida is noted for the regularity of its curls and is indeed identified by this means, yet Schaudinn observed that almost straight forms might occur, " He adds, 'These observations are sufficient to indicate that considerable doubt must be felt as to the constancy of form among the small spirochaetes, "

In the face of such differences as shown above, and the confessedly meager and uncertain knowledge of the facts on which the classification of the spirochetes and allied organisms must be made, I believe the outsider may plead even against the testimony of so authoritative a body as the International Commission on Zoological Nomenclature, that the genus *Treponema* is not so firmly fixed that, on the grounds of classification alone the name Treponema can be insisted on for any given species in the genus regardless of other considerations

There are one or two collateral points in Dr Stiles' article concerning which I should like to say a word His invoking allegiance to the findings of the Commission on Nomenclature as a matter of ethics seems to me not apposite, and, if I understand the application which he makes of it, it must, I believe, have been due to oversight Ethics scientific ethics included, concern matters of right and wrong, and I am sure Dr Stiles does not believe that any scientific commission however important, is so august that failure to accept its findings is wrong That would be medieval worship of authority

He also refers to the confusion which is liable to occur from the use of *Spirochaeta* without qualification instead of the specific name, *Spirochaeta pallida* I believe there is little danger of confusion as to the meaning in an article on syphilis if the unqualified word spirochete should be used after *Spirochaeta pallida* had first been used And I certainly see no reason why there should be more confusion from the use of *Spirochaeta* alone than that of *Treponema* alone There are already several treponemes, and the unqualified word *Treponema* is certainly not less likely to lead to confusion than the more familiar word *Spirochaeta* without qualification

A word as to Dr Stiles' remarks regarding the backwardness of physicians and their failure to appreciate the difficulties of this subject as pure zoologists do So far as the specific instance which we are now considering is concerned I do not think that it can be maintained that the pure zoologists stand as a unanimous group while the physician zoologists are chiefly responsible for the other group In looking up the position of authorities on this subject I took the first that came to hand They were Novy, Metchnikoff, Calkins Fantham, and Bosanquet Two of these five are not physicians (Calkins and Metchnikoff) and the other three while physicians are specialists in this field who have done original work of the highest class and I have no doubt could claim equal appreciation with the purest systematists of all of the difficulties of classification and nomenclature The physician zoologists are not responsible for the confusion, pure zoologists are equally uncertain The confusion lies in the uncertainty of the criteria on which the classification rest

But regardless of classification, my argument in favor of *Spirochaeta pallida* is based on the fact that *Spirochaeta pallida* is established by authoratative and greatly preponderating usage The argument would be just as strong for *Treponema pallidum* if usage were in its favor Dr Stiles indicates that there is some doubt as to what is meant by best usage as regards a word or linguistic form, and says 'Best usage from the point of view of the splitters is that usage which comes closest to expressing a natural classification of the organism'—in other words, comes closest to expressing their views I venture to insist that such is not the meaning of the words "best usage' or "good usage' as they are used in this connection, but, on the contrary, that they refer solely to precedent—the use by recognized authorities of any particular word in question Good use is a technical phrase which, as such, will be found in books dealing with linguistic forms It is an accepted principle that the criterion of the standing of words is such usage—not what you, or I, or any present body of men think should be the word to describe a thing, but what the word to describe it is, as shown by good precedent.

As Barrett Wendell says in his work on English composition

> In English as in every other language the final test of what words we may use is inevitably the usage *of those who speak and write* it the test of what words we should use is the usage of those who speak and write it best in other words good use
>
> Common consent general practice is what makes the alphabet *signify anything* In this fact lies the hopelessness of the efforts now and then made by dogmatists not possessed of despotic authority to reform spelling [With equal truth we might substitute nomenclature here for spelling —W A P] The question in a given instance is not what ought to be the case but what is And to the state of things which enables us to decide in spelling as in other fashions what the case is at any given moment we give for convenience sake the name Good Use
>
> Dictionaries and grammars [or commissions on nomenclature —W A P] to be sure, may codify what exists at any given moment Regarded as codes they are invaluable but at best they are codes of common law not legislative enactments The only sanction behind them is that of practice, of usage

Thus, usage, in the technical sense of good precedent establishes proper linguistic forms, and I would point out again that usage, both in quantity and quality is overwhelmingly in favor of *Spirochaeta pallida* That point was brought out in my previous article Let me repeat here a few of the names of individuals to illustrate the quality of usage in favor of *Spirochaeta pallida*

Metchnikoff, who discovered the inoculability of syphilis in apes and by this discovery made possible the present revolution in our knowledge of syphilis used *Spirochaeta pallida* Hoffmann who was the codiscoverer of *Spirochaeta pallida* with Schaudinn, and whose name was never separated from Schaudinn's in giving credit for the discovery until after Schaudinn s death, uses *Spirochaeta pallida* Neisser, who with Wassermann and Bruck developed the serum compliment reaction for syphilis and until his recent death was our greatest authority on clinical and experimental syphilis used *Spirochaeta pallida* Uhlenhuth, whose researches in the chemotherapy of syphilis opened the way for Ehrlich and whose work "Atlas der Experimental Kaninchen Syphilis,' written in collaboration with Mulzer, is the authoritative book on experimental syphilis, uses *Spirochaeta pallida* Ehrlich used *Spirochaeta pallida* Noguchi the only other man whose work in syphilis entitles him to mention in the class with these men uses *Spirochaeta pallida* as a rule, but *Treponema pallidum* occasionally

These men of course are not a miscellaneous collection They, with Schaudinn who died within a year after the discovery of the *Spirochaeta pallida* are the men whose discoveries have made modern syphilis, and they and their followers have written *Spirochaeta pallida* into the literature of syphilis in such a way that it cannot be erased In the attempt to substitute *Treponema pallidum* the most that can be gained by the advocates of it is the use of both names for the organism Splitters and purists may use *Treponema pallidum* It is not beyond the possibilities that in time the taxonomic grounds for its use may be swept from under them and that they may be forced back to the use of *Spirochaeta pallida* But whatever they may do the universal use of *Spirochaeta pallida* in German, its overwhelmingly preponderant use in English, and its preponderant use in French mean that *Spirochaeta pallida* will continue to be the generally used name for the organism of syphilis For the sake of unanimity and clearness, the use of two names for the organism should be avoided if possible Certainly this should not be brought about simply in the interest of a system of classification, which as respects the organism in question here, is based on characteristics whose finality is not certain

Liability of Father for Services for Daughter Away from Home

(Wallace vs Cox et al (Tenn) 188 S W R 611)

The Supreme Court of Tennessee affirms a judgment holding that the plaintiff was entitled to recover from defendant Cox as on an implied contract for a surgical operation and attendance on a 17 year old daughter of said defendant This daughter and an older one were in a nearby city earning their own living, when this one became ill and the plaintiff was called in by the matron of the Y W C A building where they were boarding After prescribing for the daughter for a time the plaintiff decided that an operation was necessary to remove an ovarian tumor He had stated that the operation would be a slight one, and, when the elder daughter telephoned to their father that an operation was advised, and he inquired whether an incision would have to be made, she said that it would not, that the operation would be a slight one and he replied 'Well, then, if it must be done, it must be done ' The elder daughter testified that the plaintiff did not ask her to telephone to her father, and that she did not inform him that she had done so for several days after the operation The plaintiff testified that in performing the services, he looked to the father for compensation The father testified that he failed to hear the name of the surgeon over the telephone, that had he been informed that an incision was required, he would have gone to the city and had the operation performed by another surgeon, with whom he was personally acquainted, and that he was not asked to and did not promise to pay for the operation The operation was successful Bills were sent to the father, who paid no attention to them and suit was brought The circuit judge sitting without the intervention of a jury, held that the father was not liable The court of civil appeals divided on the question, the majority holding that the plaintiff was entitled to recover as on an implied contract which latter is the judgment here affirmed The supreme court says that the liability of a father for necessary medical attention given a child who has not remained as a member of his immediate family is a question on which the authorities are at least in apparent conflict Cases fairly supporting either of the opposing rulings of the lower courts may be found, but a number of those holding with the judgment of the circuit court take color from English cases which proceed on the principle that a father is under only a moral obligation to support his child The obligation of the parent to support his child at common law was not well defined, but in Tennessee it has been held more nearly in accord with the natural sense of justice that the obligation is not merely moral, but legal, and enforceable as a legal common-law duty It therefore follows that if the parent neglect that duty, any other person who supplies such necessary attention to the child is deemed ordinarily, to have conferred a benefit on the delinquent parent, for which the law raises an implied promise to pay on the part of the parent In this case the father did not successfully prove any emancipation of the daughter conferring on her the right to her earnings and terminating his duty to support her Her effort to earn her own support was praiseworthy and tended to lift a burden that rested on the father, and the courts should be slow to permit the fact to become a shield for his protection, at least where a full emancipation was not shown The restoration of the daughter in consequence of the surgical operation was itself beneficial to the father, since it gave the daughter ability to relieve him further, unless it be assumed to his and the law's discredit that he no longer owed the duty to receive and provide for her as an invalid in his home The modern tendency among women and girls to earn a living frequently gives occasion for absence from home, and that fact should not readily be held to deprive them of a claim to support in time of need Slight circumstances, if necessary, will be allowed to control the decision

Breach of Contract for Removal of Gallstones

(Schuster v Sutherland (Wash) 158 Pac R 730)

The Supreme Court of Washington affirms a judgment in favor of the plaintiff, who sued the defendant for alleged breach of contract for the removal of gallstones, etc The court says that it was alleged in substance in the complaint, that, December 4 the plaintiff and the defendant entered into a verbal contract whereby the defendant, a physician and surgeon agreed to perform a surgical operation on the plaintiff and contracted, warranted and promised to remove all gallstones then in the body of the plaintiff to cure him of the ailments from which he was then suffering, and to remove from his abdomen all causes of disease, of whatsoever kind or nature, possible to be removed by means of such a surgical operation, that the operation was performed the next day, that the defendant failed to remove all or any gallstones from the plaintiff's body by the operation, though a certain gallstone was present, and that the plaintiff was compelled to employ another surgeon, who performed an operation, January 30, and removed a gallstone which had not been found by the defendant Another statement by the court is that, February 7 the second surgeon found and removed a calculus from the duct known as the ampulla of Vater, and after this operation the plaintiff improved immediately, and progressed to a final recovery without a recurrence of his previous symptoms Now, as the court reads the record there was evidence tending to show that the contract was to remove all gallstones in the plaintiff's body in whatsoever place situated and all causes of disease, be the same what they might and evidence to the effect that a gallstone of the size of the one removed in the second operation could not have formed in the body within the time elapsing between the two operations If this were the contract, and the evidence concerning the time required for the formation of the stone be believed, clearly the question was for the jury, conceding that the defendant made an exploration of the gallbladder and the ducts leading therefrom If however, the court could say as matter of law that rational beings would not enter into the contract contended for by the plaintiff, and that in law the contract was one to explore the gallducts and the ducts leading therefrom and remove such as would be found, still the court thinks the question whether it was actually performed was for the jury The court thinks there was much evidence of a circumstantial nature, to be sure which tended to show that the defendant did not perform the contract even as he conceded it to be His own testimony gave rise to a doubt whether he got as far as the ampulla of Vater in his examination of the gallducts, although he did not question that this was within the field of exploration under the contract as stated by himself The evidence was contradictory, it was true, and its weight did not seem, in every instance, to be with the conclusions of the jury, but the facts being for them, we must abide their verdict The defendant did not set forth in his pleadings any different contract from that alleged by the plaintiff in his complaint, but contended himself with a general denial Under this general denial it was competent for him to show, in order to defeat a recovery, not only that he did not make the contract contended for by the plaintiff, but what the contract entered into between them actually was But his evidence did not necessary change the issues It was still incumbent on the plaintiff to recover on the contract alleged, and the court did its full duty when it stated that issue to the jury, and instructed it that there could be no recovery unless the contract was proved as alleged

Society Proceedings

NEW YORK ACADEMY OF MEDICINE

Meeting held Dec 7 1916

The President, Dr Walter B James, in the Chair

PNEUMONIA

Nature of the Disease and Serum Treatment

Dr Rufus Cole Over 500 cases of pneumonia have been studied for the purpose of determining the relative frequency of the different types of infection From 60 to 65 per cent of all cases were due to pneumococci of Types I and II, from 10 to 15 per cent to pneumococci of Type III, while the remaining 25 per cent are due to pneumococci of Type IV Studies have also been made to determine the frequency of the occurrence of the different types in the mouths of normal persons Five hundred and twenty-seven persons have been examined and pneumococci were present in the mouths of 254 Where pneumococci were present they were of the atypical group, or Type IV, variety in about 25 per cent of the cases In 17 per cent the pneumococci were of Type III, while in a very small number of cases all together less than 12 per cent, they were of the so-called fixed types, I and II Moreover in practically all the instances in which organisms of these fixed types were found in normal mouths, it was possible to trace a close association between the person harboring them and a case of pneumonia of the same type These pneumococci of Types I and II tend to disappear from the mouth after a short time, just as they do after a convalescence from pneumonia The interpretation of these facts seems to be that pneumococci of Types I and II are to be considered as specific infectious diseases, just as typhoid and paratyphoid fever In pneumonia due to organisms of Type IV, infection is probably autogenous The interpretation of the conditions as regards pneumococci of Type III is difficult These are organisms of high virulence, yet are quite widely distributed in healthy mouths and so far as we have been able to learn there have been no differences, immunologic or otherwise, between the organisms of this type found in healthy mouths and those found in disease It is evident that isolation of cases due to pneumococci of Types I and II should be observed more strictly than has previously been done In the present stage of our knowledge it is not possible to have an opinion as to whether cases due to pneumonia of Type III would be of any value or not So far as infection with Type IV is concerned, isolation would probably have no effect

Specific treatment may be carried out in one of two ways Use may be made of the so called immunity reactions or drugs having specific harmful action on the invading bacteria may be used The use of the immunity reaction to hasten recovery may be made in one of two ways First, we can attempt to stimulate the infected organism itself to produce the immunity reaction more rapidly, and to a greater extent than would naturally be the case under the influence of the infection alone The only method of doing this at present would be by the administration of vaccine, but my studies and experience convince me that little can be hoped from this method in an acute disease like pneumonia The second method by which immune reactions might be made helpful is by the administration of the serum of animals rendered immune to the disease, and this is the method which we have employed We now have a method for determining in each case the type of infecting organism before serum treatment is commenced Moreover, from the standpoint of prognosis alone, such a determination of type is of great importance Immune horse serums have now been prepared against the three important types I, II and III The serum against pneumococci of Type I is of high power, that of Type II is considerably less powerful, while that of Type III has very little effect, either in the test tube or in experimental animals So far no attempt has been made to treat patients with Type III infection with serum A limited trial has been made with serum of Type II in corresponding cases, but the results have not been promising The use of immune serum agains infections with Type I organisms has given very gratifying results and our experience indicates that with proper use this serum has great therapeutic value In the hospital of the Rockefeller Institute, seventy-eight cases have now been treated, with six deaths, a mortality of 8 per cent When this is contrasted with the mortality of 25 per cent which is observed in our cases due to Type I infection before the use of the serum was begun, and the mortality of 25 and 30 per cent in other hospitals in which the determination of the type has been made, it is evident, so far as may be judged from this number of cases, that the serum is of considerable value These results are more striking in view of the fact that, of the six patients who died, only one could have been considered as efficiently treated in accordance with our present knowledge In order to obtain the best results, certain rules must be observed The serum must be given in large amounts It must be given intravenously Its administration must be commenced as early in the course of the disease as possible and its use must be continued until the infection has been definitely overcome It is a mistake to give one dose of the serum then wait until the disease has gained great headway and then make another abortive attempt. Before administering the serum a small dose of normal horse serum should be given subcutaneously in order to desensitize the patient in case he may be sensitive to horse serum Among the treated patients the incidence of empyema has been greater than among the untreated patients This probably means that in a certain number of cases otherwise fatal, the infection, instead of becoming general, is localized and empyema results Clinical experience suggests that the serum has some antitoxic action, but methods for demonstrating this are at present unknown The fact that this serum is effective makes it theoretically possible that refinements in technic and improvements in the method of producing the serum may also make the immune serum effective in infection due to the other fixed types

Use of Digitalis in Pneumonia

Dr Alfred E Cohn One can tell that digitalis is acting before the onset of symptoms disturbing to the patient The evidence of this consists primarily in the change of the T wave of the electrocardiogram When this change take place the P-R interval begins to lengthen, but usually the T wave change comes first We have applied these criteria to a study of the action of digitalis in pneumonia We first endeavored to show whether the drug acted and then to show whether it acted beneficially We found that it required 1 gm of digitalis at 0 4 gm a day to accelerate the T wave and also the P-R time What we had then to show was that in pneumonia with fever, with enough digitalis, changes did occur, and that in pneumonia with fever with no digitalis, no changes occurred This we have now been able to show When digitalis is given, the T wave is lengthened, and the lengthening may go on to the production of heart block Without digitalis we observed no instance of heart block in about 500 cases Those cases in which it had been reported that heart block took place bore out this contention, for with a single exception all had a sufficiency of digitalis Furthermore, the evidence shows that heart block does not occur until a sufficiency of digitalis has been given When it occurs it does no ultimate harm It should usually be possible however, to avoid it We found auricular fibrillation in twelve cases out of 123 or about 9 7 per cent When it occurred, the pulse rate rose immediately high enough to alter the prospect of recovery It was also shown that in nonfebrile cases of pneumonia with auricular fibrillation digitalis caused a fall in the Vs rate This could not be expected in every case, nor could the reason for its failure to act be given easily When fever was present it did not interfere with the action of the digitalis Auricular fibrillation might develop spontaneously in pneumonia Digitalis is not responsible Auricular fibrillation might disappear even after digitalis has been taken Auricular fibrillation if controlled is not fatal Even when the disease is fatal patients recover from the irregularity before death Digitalis does not do harm and may be life saving As a result of these experiences the hospital has for the time being adopted the following rules in the treatment of pneumonia 1 Digitalis is given to all patients as a routine 2 If patients are treated early they are given 1 gm at the rate of 0 5 gm daily 3 If patients are not seen until later, they are given 1 gm on the first day 4 If an indication arises later, digitalis is given again at the rate of 0 5 gm a day until the indication is satisfied but it is not continued beyond 2 gm The study shows that digitalis acts, and that under special circumstances, which are apparently not infrequent, its action is beneficial

Treatment of Pneumonia by Ethylhydrocuprein

Dr Alan M Chesney These studies are based on twenty-eight cases, and were carried out in collaboration with Dr Henry E Moore The results show that a bactericidal action for pneumococci can be secured in the blood serum of patients if they are given an amount of the drug represented by 0 024 gm per kilogram of body weight per twenty-four hours This amount was sufficient in every case to produce the result sought for within twenty-four hours, and to maintain it constantly during treatment Furthermore it was demonstrated that the time of appearance of bactericidal action might be shortened, provided the first dose was relatively large and was followed at intervals of not more than three hours by smaller amounts Thus for a person of average size the amount administered in twenty-four hours must be 1 5 gm and during the first twenty-four hours the best method of regulation would be to give an initial dose of 0 45 gm and follow it at intervals of three hours by individual doses of 0 15 gm During the second period of twenty-four hours the drug could be given in doses of 0 15 gm The hydrochlorid was much more readily absorbed than the base, and hence is to be preferred The oral route of administration has been found to be more satisfactory than the intramuscular route since for some reason the bactericidal action appears in the patient s serum much more quickly when the drug is given by mouth than when given intramuscularly In three cases the pericardial fluid was found to equal the blood in its pneumococcidal action

DISCUSSION ON PNEUMONIA

Dr David Bovaird Jr The three main objects to be kept in view in treating this disease are First we must make an effort to control the extent of the invasion of the lungs This has been attempted by the use of external applications of various kinds by medicines and by antiseptics the bactericidal action of which it was hoped would limit the action of the bacteria in the lungs and would overcome the invading organisms Second we have sought in various ways to control the fever and other constitutional effects of the toxemia by hydrotherapy, by drugs and by fresh air Third, efforts are made toward the control of the circulation Of all our efforts made in this direction, the only thing that has survived is the use of digitalis In order to establish a foundation for comparison I have taken the records of over 200 cases of lobar pneumonia treated in the Presbyterian Hospital just previous to the introduction of the serum treatment One hundred of these cases in adults showed a mortality of 30 per cent Then we began grouping the cases along the lines which Dr Cole has described, and we found that the mortality in this series was 8 per cent, practically the same as in the 100 cases immediately preceding Within the last eighteen months we have treated fifteen cases of Group I pneumococcus pneumonia with the appropriate serum and have had a mortality of two one patient being a man aged 77 who had a complicating empyema, and the other, a patient in the surgical side of the hospital There occurred during the same period twenty-five cases in which the serum treatment was not given and these showed a mortality of 28 per cent, which would have been higher had it not been for the fact that some of these patients were children It seems that we may expect a mortality of 30 per cent in untreated cases, in the cases in which serum was given, the mortality was 14 per cent We have had three cases during the past three months that impressed us especially with the fact that the serum has some definite specific action The first patient was a man, aged 28 with a right upper lobe pneumonia whose temperature rose to 108 4 F He was given serum on the fifth day, two injections, after which his temperature fell and remained down, and he made an excellent recovery The second patient was a woman who came in on the second day of her pneumonia and received serum on the third day Her temperature fell almost immediately and remained down, though undoubtedly she had a frank lobar pneumonia The third patient was an orderly in the hospital He received serum within thirty-six hours of the onset of the disease He received two injections on the second day, his temperature fell almost immediately In forty-eight hours it reached normal and he made a rapid recovery Such experiences have been quite ample to convince every one on the staff that in pneumonia due to pneumococci of Group I we have in the serum a remedy of very decided value

Dr L Emmett Holt In times past the diarrheal diseases have taken first place in the mortality of young children In recent times, especially during the last five years in New York, there has been a steady fall in the curve from diarrheal diseases, while the curve of mortality from respiratory diseases, especially pneumonia, has steadily risen Thus far this year, for the first time the deaths from respiratory diseases greatly exceed those from diarrheal diseases To November 1 of this year there have occurred 2 246 deaths from diarrhea in infants under 1 year of age and 2 523 deaths from respiratory diseases Under 2 years the mortality from diarrheal diseases was 2 642 while from respiratory diseases it was 3,820 In addition we must take into consideration that we still have November and December to account for months in which deaths from diarrhea are infrequent while respiratory deaths are constantly on the increase The indications are that the mortality of infants under 2 years of age from respiratory diseases for the year will be at least 1,300 greater than from diarrheal diseases The deaths from all contagious diseases to November 1, including those from poliomyelitis were but 1,012, a little more than one-fourth those from respiratory diseases Pneumonia has thus clearly become the most important disease of young children This disease at this age is not often the clear cut lobar pneumonia due to one of the four groups of pneumococci, which one meets in the adult, it is usually a mixed infection There are found other organisms which add much to the severity of the disease and modify its clinical course, making it less amenable to treatment than the same disease in the adult Observations made at the Babies' Hospital have shown that about 75 per cent of the pneumococcus infections in children under 3 years of age belong to Group IV It therefore seems that serum treatment as yet offers little prospect of help in pneumonia in the early years of life, first, because one so frequently has to deal with a mixed infection, and, second, because the pneumococci most often belong to Type IV Against this as Dr Cole has shown it is obviously impossible to provide a specific serum Children frequently show pneumococci of Type IV probably because of the wide prevalence of the organism and the extreme susceptibility of the patients This brings up the question of the prevention of respiratory disease in young children It is known that many adults harbor pneumococci of Type IV, but do not develop the disease Many times a child may at first show only the respiratory symptoms of a common cold, and yet pneumonia will supervene and may prove fatal, not because of the virulence of the infecting organism, but because of the susceptibility of the individual

Dr Robert H Halsey Cases of pneumonia may be divided into two classes first, those in which the heart shows no difficulty as the disease progresses, and, second, cases in which changes in the heart occur In the great majority of the cases of the first class it is unnecessary to use digitalis I am convinced of this because I have worked with the electrocardiograph and know its value in recording and measuring the changes There is, however, a time when digitalis is necessary But if digitalis is used in every case, heart block will develop in some of the cases, as has been demonstrated One does not seem to be justified in such cases in adding an additional burden, of dissociation of auricle and ventricle, to a heart already under stress The cases with fibrillating auricle may be divided into those that have the fibrillation before the disease starts and those in which the fibrillation starts after the disease has begun In the latter class of cases, digitalis controls the condition nicely, and should be used until control is obtained In the former class, which has the fibrillation before the disease starts and will have it afterward, digitalis is indicated and should be employed if required, to retain control while in health

Dr Arthur F Chace A word of warning should be sounded against the use of stock polyvalent vaccines The polyvalent vaccine offers a great temptation to the general practitioner, and emphasis should be laid on the fact that it is impossible to provide a stock vaccine that is of dependable therapeutic value It is possible to accomplish much if we avail ourselves of the combined action of serum and ethylhydrocuprein

Dr Rufus Cole I object to the use of the polyvalent serum because it is an additional burden on the patient without the production of any good result

WESTERN SURGICAL ASSOCIATION

Twenty Sixth Annual Meeting, held at St Paul Dec 15 16 1916

The President, **Dr L W Littig**, Davenport, Iowa, in the Chair

New Instrument for the Application of the Sewing Machine Stitch in Gastric and Intestinal Surgery

Dr E P Quain, Bismarck, N D The results in forty cases have been very satisfactory Leakage is effectively prevented by this double, interlocking suture The time previously consumed for making a gastro-enterostomy has been reduced by nearly one half To prove the hemostatic efficacy of the method in gastro-enterostomy, a gastric lavage was given to the patients with duodenal ulcer immediately after the operation and repeated about two hours later With the exception of a few shreds of clots in two or three instances, such as might easily have escaped during the operation performed without clamps, there was no macroscopic evidence of oozing Occasional emesis after the operation gave the same negative evidence Previous observations with other methods of suturing had rarely, if ever, shown such complete absence of bleeding in the postoperative vomitus

Serous Meningitis Following Traumatism

Dr Charles H Lemon, Milwaukee, Wis A man fell 40 feet from a coal dock and was picked up unconscious with a compound fracture of the right wrist He remained unconscious only a few minutes, was removed to a hospital, was operated on for the fracture under an anesthetic, and for five days was apparently normal On the sixth day he began to have headache and this was followed by a progressive right hemiplegia, which was complete on the ninth day Believing that he had probably fractured his skull on the left side and that a hemorrhage was taking place from the posterior branch of the middle meningeal artery, I advised an operation to remove the blood clot This was declined The following day the man became totally unconscious, and when he was in a state of coma, permission was given to operate I trephined the skull over the middle fossa and found no clot The cortex of the brain, on the opening of the dura presented an ecchymotic appearance No cerebrospinal fluid appeared I passed a grooved director between the dura and brain, and a few drops of cerebrospinal fluid escaped In a few minutes this increased to a small stream At the end of fifteen minutes the patient began to show signs of life The breathing improved The operation was performed without an anesthetic A drain was inserted beneath the brain and the wound closed The man made an uneventful recovery and is still living

DISCUSSION

Dr A E Halstead, Chicago My conception of a serous meningitis is entirely different from that of Dr Lemon's A serous meningitis, as I understand it, is caused by a toxemia or a mild infection in which there is no pus or no gross manifestations of infection in the meninges I have operated in several of these cases I have also seen cases of diffuse meningitis in which the fluid was still serous or retained the characteristics of normal cerebrospinal fluid These cases occurred in the terminal stage of an infection I think a weak point in the doctor's paper is the fact that he has no necropsy to sustain his diagnosis of such a traumatic serous meningitis

Dr John L Yates, Milwaukee, Wis In these cases of increased intracranial pressure, when there is no foreign body, there is a disproportion in the amount of cerebrospinal fluid secreted and the amount of fluid absorbed This may be the result of irritation, chemical or bacterial infection, or trauma

Dr Frederick A Dunsmoor, Minneapolis Dr Frank Hamilton, in 1873, impressed on me the point that whenever a man who has had a slight injury of his head is bewildered, or even unconscious for a moment, and then gets up and walks off, there is a grave possibility of tragic symptoms developing later

Dr M M Ghent, St Paul Dr Halstead said that we have no postmortem reports to sustain the diagnosis of traumatic serous meningitis One drunken miner struck another on the back of the head with a large rock The man was stunned, I saw him about five minutes afterward He was able to talk There was a slight abrasion, not more than half an inch long, just back of the ear He was put to bed On the second day he complained of headache, on the third day he had a little fever and began vomiting He was taken to the hospital, and lived seven days We opened the skull and found no fracture, no hemorrhage, but the brain on the injured side was just like putty, while the opposite side seemed to be entirely normal

Cardiolysis

Dr John E Summers, Omaha Cardiolysis, first performed by Peterson at the suggestion of Brauer, in 1902, is done in cases of chronic adhesive mediastinopericarditis The heart muscle in two cases reported by me was in an advanced, degenerated condition Nothwithstanding this, one patient, a man, lived four years and ten months after operation, was able during this period to earn his living and was almost free from heart symptoms until the last several months of his life The second patient, a young woman, lived nearly a year after operation, had symptomatically made a recovery so far as the function of the heart was concerned, being able to drive a large automobile from Omaha to Denver, 600 miles, cross the Rocky Mountains, and travel to a height of 12,000 feet without discomfort Overstrain however, brought on an attack of decompensation which proved fatal

DISCUSSION

Dr William R. Cubbins, Chicago Dr Summers is to be congratulated on undertaking operative interference in this case There is no question that the relief will be marked when we have enough courage to remove the chest wall as it should be done

Dr R C Coffey, Portland Ore Not all of these cases have been reported Dr William J Mayo and I were attending a clinic in New York when we saw this operation performed by a prominent surgeon The anesthetic was intratracheal, and just about the time the chest wall was completely removed the patient closed his eyes and never breathed again That case has not been reported

Dr George M Gray Kansas City, Kan In another case I resected, as I remember, the fourth fifth and sixth ribs The operation was done about a year ago under local anesthesia The patient, a man aged 32, improved markedly

Factors Which Determine the Extent and Duration of Peritoneal Adhesions

Dr Arthur E Hertzler Kansas City, Mo The principles governing the formation of adhesions are the same as those which pertain to wound healing The exudate forming about wounded surfaces must coagulate to form fibrillar fibrin as the preliminary step If this is interfered with, primary healing does not take place Permanent adhesions correspond to healing by first intention, while temporary ones parallel healing by second intention The purpose of permanent adhesions is to repair solutions of continuity, while temporary adhesions serve the purpose of preventing the spread of infection When repair is desired, the factors inimical to blood coagulation must be kept from the site of the wound Temporary adhesions release themselves after their function has been performed, and it is not necessary to break them up when operating in infected tissue in order to prevent subsequent deleterious consequences

Position in Abdominal Drainage

Dr Roland Hill, St Louis The lateral position, in which the patient is placed on the right side, is very efficient In this position the head of the bed is slightly elevated, about 30 degrees, and a pillow is placed under the region of the liver, so as to prevent accumulation of fluid in the kidney region In a series of fifteen cases treated in the lateral position, there was an absence of mortality In a series of forty-two drainage cases treated in the abdominal position, there were two deaths In forty-seven cases treated in the Fowler position, there were five deaths

Radical Cure of Chronic Osteomyelitis

Dr Emil G Beck, Chicago I have adopted the following plan in dealing with these cases First, I try the most conservative treatment, namely, the injection of bismuth paste, and am able to clean up 60 per cent of the cases If this method has been given a fair trial for several months and there is no improvement, the remaining 40 per cent of cases are treated by a most radical operation I expose the diseased area by an adequate skin flap incision that I may remove every vestige of the diseased bone, under ocular inspection I do not permit any dead space in the resected cavity, and I remove enough bone to make a flat surface of bone Then I implant the skin flap against the bone, packing gauze against it to keep it in contact I use no suture material, and leave the wound widely gaping and permit granulations to form on the denuded surfaces The skin on the granulating surfaces is reproduced by means of adhesive plaster dressing, which is changed daily and is the best form of epidermization of large denuded areas I use no skin grafts

Traumatic Surgery of Liver

Dr Oliver J Fay, Des Moines, Iowa Operations on the injured liver should be performed with all the speed compatible with gentleness and a thorough examination of the abdominal viscera Temporary control of the hemorrhage is usually to be obtained by tamponing Suture of the wound, ligation of the larger vessels, and tamponing are the most serviceable definitive procedures Tamponing is the method employed in the largest number of cases, it effects temporary hemostasis until other measures can be employed, it controls hemorrhage from wounds which are inaccessible or which could be reached only by an unwarranted incision, it is the least time consuming procedure, and is the method of choice when the patient is in a precarious condition, and speed is the first essential It is a valuable adjuvant to suture of a wound when hemostasis is not assured, or the possible presence of other liver injuries cannot be excluded, and in every case in which the simple ligation of vessels has been employed it is essential when the presence of infection cannot be excluded

The Open Hospital

Dr Lawrence W Littig, Davenport, Iowa The most important problem before the medical profession at the present time is the investigation and classification of hospitals The possibility of such investigation has already produced fruit, and signs of life are already evident in hospital boards and hospital staffs that had long been dead so far as the spirit of improvement and progress is concerned The fifth or intern year, as already adopted by an increasing number of medical schools and state boards, will have even a more decided influence for good in the hospitals that desire interns, since both the college and the state board will *insist on* knowing about the character of the work done in a hospital before it is put on the accredited list But there are many hospitals that *do not care* for interns, and these can be reached by the state board through the training school, since practically all of the hospitals under consideration conduct training schools, the graduates of which present themselves before the state board for examination for credentials as registered nurses Publicity is the only influence that will reach all of the hospitals under consideration, and stimulate all hospital boards and hospital staffs to action

Cyst of the Suprarenals

DR HERMAN E PEARSE Kansas City, Mo Hemorrhage is the foundation of the pathogenesis of suprarenal cysts The fully developed cyst is usually, as in my case recognized only when the hemorrhage has been repeated from time to time, and operation is at last done for a demonstrable tumor The condition of suprarenal hemorrhage being concealed retroperitoneal and not showing in any excretion of the body, must of necessity be occasionally unrecognized in its early stages and may often if suspected and looked for, be recognized as the foundation of phenomena otherwise quite puzzling to the examiner

Surgical Treatment of Banti's Disease Report of Three Cases

DR CHARLES D LOCKWOOD, Pasadena Calif I have collected reports of thirty-eight cases from the literature which with three cases of my own make forty-one in all Six of these patients died as a result of operation, making an operative mortality of 14 5 per cent Operation done in the first stage of the disease is curative in a large percentage of cases and the operative mortality is no higher than in other major abdominal operations In the second and third stages of the disease, there is still a large percentage of recoveries with great improvement of health

Intracanalicular Papilloma of the Breast

DR E STARR JUDD Rochester, Minn In fifty of 100 consecutive cases of discharging nipples, a serohemorrhagic discharge was present, and in the remaining fifty some other form of discharge was described Carcinoma appeared to be the most common lesion producing a discharge from the nipple, it was almost invariably associated however, with a tumor in the breast Usually the tumor was present some time before the discharge began In 26 per cent of these cases chronic cystic mastitis was present, twelve of them were in the first group of fifty, and fourteen in the second In some of our cases of chronic cystic mastitis, however, the discharge may have been from a duct papilloma, for often these tumors are very small and might easily have been overlooked This series seems to lend evidence to the contention that a hemorrhagic or serohemorrhagic discharge from the nipple in the absence of a palpable tumor is most often produced by benign intracanalicular papilloma In view of this fact, treatment should be conservative particularly in young women In older patients especially if the condition is associated with chronic cystic mastitis, the mammary gland should be removed If there are indications of malignant changes, a radical operation is advisable

The Radical Cautery Operation in Breast Carcinoma

DR JAMES F PERCY, Galesburg, Ill The most important improvement that can be made in the technic of the modern operation for breast carcinoma is the use of the hot knife in place of the cold steel knife The wound should be left open in order that small points of recurrence may be watched for which, if they appear, can be cocainized and treated by heat at once After the wound has been made, no matter how extensive, epithelization can be hastened by covering with strips of adhesive plaster, as recommended by Beck Carcinoma is most prone to recur wherever blood vessels are left in the wound Practically every recurrence is about a blood vessel I would urge that no bleeding vessel be clamped with a hemostat, but it is more important that the bleeding should be arrested by the application of the cautery knife, which not only stops the hemorrhage, but also kills the most common origin for the cancer nidus in its incipiency I would advise that a roentgenogram be made of the thorax If metastasis into the lung pleura or ribs is disclosed, the treatment should consist of massive doses of the Roentgen ray administered by an expert roentgenologist The four most essential points in the technic are, first, to mark out on the iodin covered skin surface with the handle of the steel knife the limits of the incision to be made, second, do not cut with the cautery knife from above downward into the skin in following this line, but from within outward, third, and very important, in dissecting about the axillary vessels and brachial plexus, hold the parts that are to be removed with the fingers of the free hand, encased in a medium weight rubber glove, and keep the fingers close to the cautery knife This is the most practical way of gaging the degree of temperature that the tissues and blood vessels will stand without being injured Fourth, apply the heat until all the tissues that were fixed by the disease are freely movable To do otherwise simply means that heat dissemination in the most effective way has not been obtained

16, 17 and 18 **Afferent Spinal Paths and Vasomotor Reflexes**—Experiments made by Ranson and Billingsley resulted in the following observations Afferent pressor impulses travel up the spinal cord in the apex of the posterior horn on both sides of the cord but somewhat better homolaterally It is probable that a small portion of the pressor impulses passes directly forward through the gray matter to the efferent vasomotor neurones of the white rami Most of the pressor impulses ascend through the apical path in the posterior horn to the vasoconstrictor center of the brain There is some evidence which points to the location of the reflex vasoconstrictor center in the region of the fovea inferior in the floor of the fourth ventricle The efferent path from the vasoconstrictor center to the vasomotor neurones of the white rami is located in the ventral or lateral funiculi The depressor path is located in the ventral part of the lateral funiculus and its conduction is bilateral, although somewhat better on the contralateral side as indicated by the results of hemisection There is some evidence that a separate vasodilator center may exist in the region of the area postrema lateral to the obex in the floor of the fourth ventricle Weak stimulation of an afferent spinal nerve causes a drop in blood pressure which is a true vasomotor reflex and independent of respiratory movements A drop in blood pressure obtained from strong stimulation may be due to excessive respiratory movements True pressor reflexes are produced only by strong stimulation There is little evidence in favor of the conception of two kinds of afferent vasomotor fibers and considerable evidence against it

The glossopharyngeal and vagus nerves and the depressor branch of the latter are all visceral nerves and are connected with the visceral afferent column in the medulla, while the fifth cranial and the spinal nerves are all connected with the somatic afferent column This difference in the central connections of the two groups of nerves is sufficient to account for the difference in the vasomotor reactions obtained from them No clearly defined path for afferent impulses to the respiratory center could be found The fibers which carry these impulses seem to be somewhat widely scattered in the cord In the cat pain conduction in the spinal cord is bilateral and effected through a series of short relays For a few days following bilateral injury to the apices of the posterior gray columns there is hyperesthesia of the hind limbs and all parts of the body behind the lesion

20 **Effect of Epinephrin on Coagulation**—Grabfield found that the intravenous administration of minimal doses of epinephrin (0 143 c c of a 1 100 000 solution per kilo) decreases coagulation time by increasing the amount of prothrombin in the circulating blood

23 **Osteogenesis in Light Vital Staining**—Young and growing animals were stained by Shipley and Macklin with azo dyestuffs and metallic colloids and the young osseous tissue was studied A report of such a histologic study is presented in this paper The avidity with which cells eat the vital dye granules places them in the category of macrophages and demonstrates the phagocytosis of which they are capable The osseous tissue is stained very darkly and this color is much more marked in the growing than in the fully developed bone Especially dense staining marks the actively growing areas of the bone The primary ossification centers are stained only if they are areas of osteoblastic activity at the time of the giving of the dye This is most evident in the thin bones of the developing skull where the primary centers are almost without color and the rapidly advancing edge of the membrane bone is heavily stained It was expected that the osteoclasts would be found loaded with blue granules Instead of this no blue at all was to be seen in their bodies In other words these cells are nontrypanophilic and nonphagocytic They can therefore not be classed with the pyrrhol cells on a physiologic basis

The only cells which manifested the characteristic trypanophil reaction were the ordinary reticulo-endothelial cells of the marrow reticulum Though these were everywhere present throughout the marrow cavities of the young bone, they seemed to be most numerous in the areas where erosion of cartilage and bone was going on most actively At the margin between cartilage and bone at the epiphysis there was a narrow zone in which these macrophages were very numerous, and a distinct line of them could be made out along the edge of the cartilage to which they were apparently closely applied In a region of the new endochondral bone, just behind the advancing osseous border namely, in the region in which the new spicules of endochondral bone were being most actively resorbed, they were more thickly grouped than in the rest of the marrow cavity The pyrrhol cells or macrophages may therefore be considered to take some part in osteogenesis and it is believed that they ingest the debris and assist in clearing it away Any office of the osteoclasts in the resorption of calcified cartilage or bone must be performed by the agency of chemical solution or mechanical erosion through pressure exerted by them on the material which is being broken down

25 **Influence of Vagus on Auricle**—The depression of the mechanical contraction of the mammalian auricle which follows vagal excitation, Wiggers says, is due to an actual decrease in the contraction of the individual cardiac units The decrease is not secondary to changes in rhythm or to alterations in conductivity The decrease may be favored by the depression of irritability produced by vagus stimulation but is primarily due to the depressant effect of the vagus on the function of contractility

26 **Time Relations of Auricular Systole**—About 0 02 second after an impulse is emitted from the sino-auricular node the right auricle begins to contract as evidenced by the rise of intra-auricular pressure The precise onset of this mechanical shortening Wiggers says cannot be determined from the waves of the venous pulse, but may be approximated by the peak of the P wave taken by Lead II This mechanical shortening is due to a series of fractionate contractions which spread across the auricle in the wake of the excitation wave The auricle continues to shorten as long as the contracting units of cardiac tissue overbalance the relaxing units As soon as an exact balance is established no further shortening is possible and the termination of the systole has come This period lasts about 0 11 second The contraction of the auricle exerts a dynamic action by elevating intra-auricular pressure This occurs early in systole but continues for only 0 05 second, during the remainder of systole the intra-auricular pressure falls This dynamic interval, as the period during which pressure rises is called, may be estimated from the rise of the presystolic wave of the venous pulse, a-wave, but the total duration of systole can be determined neither from the venous record or the electrocardiogram

The auricle continues to contract after excitation of the ventricle has occurred as shown by the fact that it terminates during the R variation of the electrocardiogram The ventricle normally never contracts until auricular systole is completed Occasionally ventricular systole follows immediately but usually an intersystolic interval, averaging 0 024 second, intervenes The duration of this interval can be accurately determined neither from the jugular tracing nor from the electrocardiogram The a-c interval of the jugular pulse in normal and regular rhythms very nearly equals or at least varies with the A_s-S_s interval, but the latter is not a criterion of the intersystolic interval and does not vary with it

29 **Vagus Nerves in Pneumonia**—Since the respiratory disorder in pneumonia is manifested both in the lungs and in the respiratory bulbar center, and since these two are connected by the vagus nerves a causal relation between the dyspnea and the exhaustion of the respiratory center was sought by Porter and Newburgh by section of these nerves This procedure led to the discovery that section of the vagus

nerves protects the respiratory cells and prevents their exhaustion in pneumonia Moreover in pneumonic dogs in which both vagus nerves have been cut, the rate of respiration remains normal

39 Felons G M Dorrance, Philadelphia—p 716

30 **Tissue Fragments and Wound Infection**—With a view to determining the relative importance of a foreign body and of dead tissue in the initiation and rate of extension of infection in wounds, experiments were undertaken by Taylor The implantation of a sterile foreign body or a small piece of sterile dead muscle alone produced no macroscopic lesions The implantation of a foreign body infected with tetanus bacilli, *Staphylococcus aureus B aerogenes-capsulatus*, or streptococci produced usually a localized abscess formation without invading the surrounding normal tissues The addition of a small portion of dead muscle tissue in the region of the infection produced a more rapid and diffuse inflammatory process with earlier and more extensive abscess formation than the wounds containing only bacteria or those containing infected cloth The implantation of infected cloth together with muscle tissue produced a more active and destructive lesion than the implantation of either alone When infected with tetanus bacilli the presence of dead muscle fragments determined a high mortality Of the two substances, cloth and devitalized muscle, in the presence of infection, the muscle produced the more acute infective process The result of these experiments suggests that in the cleaning of fresh wounds at least as much care should be exercised to remove separated and devitalized fragments of soft tissue as is taken to remove other foreign bodies In all operative procedures where blunt dissection is practiced it should be remembered that torn fragments of devitalized tissue may remain to become a ready soil for the incubation of any bacteria which may gain access to the wound

31 **Blood Pressure During Ether Anesthesia**—The purpose of Muns' investigation was to demonstrate graphically the actual changes in the condition of the peripheral circulation and in blood pressure accompanying long continued ether anesthesia, and the relation which the vasomotor changes may have to the blood pressure He found that ordinary third stage ether anesthesia prolonged beyond one hour results in more or less marked vasodilatation in the periphery This is a progressive change more or less regular in character, increasing *directly in proportion* to the lengthening time of administration In most cases the limit of vasodilatation is not reached seven hours after the beginning of the anesthetic, but occasionally the extreme of the condition may be reached after a shorter administration of ether There is a direct relationship between the condition of the vasomotor control and the blood pressure The end-result of ether *depression is* loss of function The syndrome, known as postoperative shock, is a combination of the effects of excitation and depression, and varies directly with the algebraic sum of these two factors The vasomotor center is the variable factor in bringing about the vasomotor change, the variation is directly dependent on the changes in the vasomotor center produced by ether

34 **Tooth Germ Cysts of Jaw**—Cystic tumors of the jaw are divided by Wohl into (*A*) inflammatory, (*B*) tooth germ (chorioblastoma), (*a*) unilocular, (*b*) multilocular, (*c*) solid Chorioblastomatous cysts of the jaw originate from the embryonal rests of epithelial cord of enamel organ

35 **Thoracic Aneurysm Wired**—Both cases cited by Lusk were given antispecific treatment after the wiring operation and they developed an ability to endure very severe exertion Special attention is called to the need for treatment of aneurysm with the antispecific remedies

68 Case of Darier s Disease (Keratosis Follicularis) in Its Early Stages M Scheer, New York—p 837

66 **Calamine Liniment**—In order to overcome the drying effect of a simple calamine lotion, Pusey uses a liniment whose formula is practically that of the common calamine lotion with the addition of olive oil and enough tragacanth to make a permanent emulsion The essential feature of this liniment is that by utilizing the emulsifying action of

tragacanth a permanent emulsion is produced which maintains an even mixture of all the ingredients The formula for this liniment is as follows

		gm or c c.	
Pulvis tragacanthae		4	ʒ i
Phenolis et glycerini (mixed)	aa	66	♏ x
Zinci oxidi et calaminis	aa	30	℥ i
Ol olivae		120	℥ iv
Aquam	q s		O i
Ol bergamoti			gtt xxl

The few drops of phenol keep the liniment sweet indefinitely The formula gives a thick emulsion, like very thick cream or a cod liver oil emulsion If a thinner emulsion is desired an equally permanent one about the consistence of ordinary cream can be made by using ½ dram of tragacanth, instead of a dram, to the pint

73 *Intentional Hypertonia Cortical Localization of Muscular Tonus S I Schwab St Louis—p 510
74 Epileptic Dementia with Recovery D A Thom, Palmer Mass—p 517

69 **Hyperplasia of Pineal Body**—The pineal gland in two cases was examined by Bell In each instance it was enlarged and contained cysts Bell says that in none of the organs of internal secretion are there cells with characters similar to those of cells of the pineal body The pineal cells in young individuals are similar in number and structure to those in pineal bodies of older individuals after involution is established Pineal cells are intimately related to fibers which resemble those of neuroglia and there are transitional forms between neuroglia cells and pineal cells Pineal cells appear to be modified neuroglia cells In association with the process of involution there may be tumor-like enlargement of the pineal body characterized by proliferation of the pineal cells In association with hyperplasia of these cells there is no functional disturbance in other organs of the body

71 **Posterolateral Sclerosis Following Streptococcus Infection**—The first patient whose history is cited by Williams had the symptoms of a posterolateral sclerosis with no definite or evident cause Six old roots in the anterior lower jaw were removed and a culture made A hemolytic streptococcus was found which injected into a rabbit gave a posterior paraplegia with incontinence of urine and feces fourteen days after the inoculation Further culture from the cord did not show anything as the rabbit was probably killed too soon after the occurrence of the paralysis (third day) The cord showed an area of myelitis and softening

73 **Intentional Hypertonia**—By intentional hypertonia Schwab means this muscle groups which in a state of flaccidity or semiflaccidity shows *to palpation no spasm* of contracture whatever, when they become the subject of intended movement associated with emotion or desire show incontestable evidence of hypertonia just as hypertonic muscles are seen as the result of resistance movements There is therefore overaction adductor attitudes, flexor overaction at the elbows, and all the phenomena which accompany innervation both as to gait attitude, facial expression etc This condition of intentional hypertonia is unaccompanied by any evidence, so far as the reflex or the existence of plantar extension is concerned of involvement of the pyramidal tract except in one case When the patient is at rest or when volition intention or emotion are not in force the patient s arms and legs are flaccid hypotonic and relaxed Schwab has seen five such cases, four patients showed some degree of mental deficiency

107 **Urethral Stricture**—A stricture, Peterkin says signifies swelling infiltration not cicatricial contraction What is the most common, yet most efficient factor, in reducing swelling, infiltration? Hot water! Every physician and surgeon, therefore, should remember the efficiency of hot water in treating stricture mechanically, also they should remember the stopcock, the compressor urethrae, is a voluntary muscle and teach the patient to irrigate the entire urethra under hydrostatic pressure, not with a catheter, but with a glass nozzle doing this at home, using a very hot mild antiseptic solution three or four times daily between mechanical treat-

ments and practically discontinuing the same after the mechanical treatments have ceased Then note the quick subsidence of the infiltration, and of the symptoms, and the increased percentage of cures For strictures that have become strictures and are strictures requiring no delineation, no science, in diagnosis, the remedy is operative

115 *Occurrence of Acetone in Urine of Acutely Insane G W Mills and R G Wearne Central Islip—p 433
116 Mental Regression Its Conception and Types F L Wells, Waverley Mass—p 445

114 **Alzheimer's Disease**—Lambert cites two cases, both men of 49, without significant heredity or make-up, but with a history of alcoholism In each there developed slowly and insidiously without attacks of unconsciousness or convulsions, a most profound dementia The onset was first evident in inattention, indifference and absentmindedness, later became more manifest in declining efficiency, progressive impairment of memory, retention, grasp and poverty of thought, followed by aimless restless, foolish behavior and increasing mental dilapidation which went on apace toward an apathetic dementia, incapacity to comprehend, to talk to walk and a bedfast state in which the patient muttered and mumbled and fussed and fumbled and pulled at his bedding wet and soiled himself, chewed a little and gulped what was put in his mouth and vegetated for a time and died like a decerebrated animal Among the more striking symptoms in these cases were the outstanding symptoms of agnosia aphasia and apraxia In two other patients one 61 and the other 71, there likewise developed gradually, without cerebral irritation, apoplexy or paralytic phenomena, evidences of deterioration In addition to the diffuse nonsystemic symptoms of dementia there stood out in the first case a diffuse aphasic or paraphasic disorder, largely of a sensory type at first, later of both a sensory and motor transcortical type There was little motor or ideatory apraxia in this case In the second case there was also considerable paraphasia and jargonaphasia but more prominent were the symptoms of motor, more particularly ideatory apraxia There was absence of objective paralyses, although in the second case a right hemianopsia was suspected and anatomically properly so

115 **Acetone in Urine of Acutely Insane**—In necropsy material Mills and Wearne noted the regular appearance of casts and albumin prior to death, and postmortem they found various kidney changes, which, at least in some cases, seemed the most important pathologic finding It, therefore, seemed that a kidney irritant or toxin was at work The authors then found that the urine in these acute cases often contained acetone, that the acetone would appear before the casts and albumin Treating these cases from a nephritic viewpoint was entirely unsuccessful but from a gastro-intestinal auto-intoxication standpoint they had very fair success The appearance of acetone indicates a metabolic disorder, probably dependent on a gastro-intestinal condition, and also an inherent personal fault Its appearance shows that the toxemia is reaching a stage when ill effects on the kidneys may be expected These will be shown simultaneously, or, in a few days, by the appearance of casts and albumin, and there is apparently some danger of the kidney change becoming chronic Patients treated along expectant and symptomatic lines died Treatment to improve renal functions including diuretics, stimulants, baths, packs cathartics, rectal irrigations, hypodermoclysis, etc, failed Alkaline treatment, such as the administration of large amounts of soda, also gave very little benefit The treatment eventually resolved itself into free catharsis, free washings of the lower bowel by enemas or, preferably saline irrigations, forcing fluids as much as possible, *forced feeding* with skim milk and cereals, usually oatmeal gruel and addition of either cane sugar or lactose, use of intestinal antiseptics, preferably either thymol or betanaphthol, stimulation where necessary, sponging for temperature and other routine measures as in any serious illness

7 *Projectile Injuries of Blood Vessels W Pearson—p 796
8 Physiologic Work of Ivan Petrovich Pavlov W M Bayliss—p 799

2 **Arsenic Cancer**—A woman aged 60 came under Bland-Sutton's care with a large ulcer just below the left knee, it had the usual signs of cancer of the skin In shape and position the ulcer resembled a patch of psoriasis The scaly, onion-like patches peculiar to this disease were present on her legs and elbows She had suffered from psoriasis for thirty years and during this period had taken arsenic more or less continuously In 1913 a pimple appeared at the lower border of a scaly patch on the skin, just below the patella This pimple gradually became an ulcer that was frequently scraped and cauterized In spite of this treatment it increased in size, in 1916 it had become a typical cancerous ulcer as big as the palm There were enlarged lymph nodes in the groin August 23, Bland-Sutton removed the lymph nodes from the groin, ligatured the common femoral artery resected the upper 2 inches of the internal saphena vein at its junction with the femoral vein and amputated the limb through the middle of the thigh Tissues from the edges of the ulcer had the microscopic characters of squamous celled cancer but there were no cell nests The big lymph nodes from the groin were examined and found free from cancer but they showed the changes common to nodes enlarged from septic infection The patient made a quick and satisfactory recovery after the amputation

3 **Gunshot Wounds of Blood Vessels**—Treatment of a series of twenty-one cases has suggested to the authors the conclusion that bullet wounds of large blood vessels coming under observation on an average four weeks from the date of injury most frequently show signs of either diffuse false aneurysm or arteriovenous aneurysm, and that the former and more urgent cases can be treated successfully by a local operation at this period, provided that the circulation above can be controlled efficiently either by tourniquet, digital compression, or, in the case of the upper extremity, by ligature of the main artery at some point above the lesion Fifty per cent of arteriovenous aneurysms benefit, temporarily at any rate, by delay in operative treatment, considering the known results of operation in these cases Where the advent of sepsis is suspected in cases of diffuse false aneurysm free drainage after operation is unattended by danger of secondary hemorrhage Efficient collateral circulation is established in most cases of destructive gunshot arterial lacerations within a month of the date of injury

5 **Operations Under Spinal Anesthesia**—For operations on the abdomen and lower limbs the lateral posture was used for the injection, for perineal, the sitting-up posture The height of anesthesia reached in each case was carefully noted and found to be usually the nipple line, although in some cases it extended a little higher The average time at which anesthesia was complete was found to be three and a quarter minutes, the moment of injection being carefully recorded in each case The duration of the anesthesia was found to be ample for the cases under consideration, lasting usually fifty to sixty minutes, though in some cases longer Three complete failures to obtain anesthesia occurred, but in each of these Weston believes that he was to blame for faulty technic, as they were all early cases No failures occurred in the later cases No serious untoward effects were observed either during or after the injections A few patients experienced slight dyspnea during abdominal operations if the anesthesia reached above the nipple line, but this disappeared rapidly on slightly elevating the shoulders and head Slight headache occurred in one or two patients after operation, but was immediately abolished by the administration of phenacetin and caffein Weston says that if the patient be moved with extreme care no headache occurs In each case Barker s stovain glucose solution was used

7 **Projectile Injuries of Blood Vessels**—During the past nine months Pearson has operated on fourteen patients for lesions of the blood vessels All cases of aneurysm and a case of varicose aneurysm were treated by intrasaccular operation In one case (popliteal aneurysm) restorative endoaneurysmorrhaphy was performed in the others “transsaccular ligation’ was necessary, although in three of them suturing operations were at first attempted, and in one of these restorative endo-aneurysmorrhaphy was actually completed before it was recognized that the case was complicated by the addition of aneurysmal varix There was no mortality in the series, and in every case the vascular lesion was cured

9 *Histology of Disseminated Sclerosis J W Dawson—p 377
10 *Marked Spastic Paraplegia of Fifteen Years Duration Death Due to Diabetes Mellitus and Boils B Bramwell and J W Dawson—p 411
11 Action of Veratrone in Treatment of Eclampsia, Report of Three Cases W F T Haultain—p 416

9 **Histology of Disseminated Sclerosis**—The tentative nature of the explanations on many points, and the fact that no uniform conception of the process can be offered have been taken into account in formulating the following conclusions drawn by Dawson The process underlying disseminated sclerosis is a subacute disseminated encephalomyelitis, which terminates in areas of actual and complete sclerosis There are no sufficient grounds for distinguishing between primary and secondary forms of disseminated sclerosis There is much to favor the view that true disseminated sclerosis is due to a specific morbid agent which calls forth a clearly defined clinical and anatomic picture other disseminated affections of the central nervous system, such as disseminated arteriosclerotic syphilitic, endarteritic and acute encephalomyelitic processes may all produce a symptom complex very similar to that of disseminated sclerosis, but they, in their further course differ from the later in the characteristic remissions and relapses, and further, acute infective diseases, trauma, chill, shock and all known exogenous factors may act as exciting factors in lowering the resistance of the organism, and thus allowing the final determining factor to operate

The causal agent is of the nature of a soluble toxin and it is conveyed to the nervous tissues probably by the blood channel rather than by the lymphatics The restriction and distribution of the pathologic process is in some way related to the selective action of the toxin on certain areas of the blood supply, or unknown factors determine an irregularly distributed paralytic dilatation, with an increased filtration through the vessel walls Remissions and relapses necessitate the assumption of the latent presence of the morbid agent in the body, or, if this is an autogenous toxin, either its intermittent evolution or its accumulation from deficient elimination

It is suggested that fleeting early motor paralyses and psychic symptoms may be related to the presence of areas in association paths, that remission of these symptoms is possibly due to the linking up of other association paths, or their compensation by the opening up of new paths, and further that the variation of the symptoms in all stages of the disease emphasizes the importance of the mental factor in the symptomatology that the cortical areas share in the production of psychical symptoms that volitional tremor, alterations in speech, and nystagmus may be the result of sclerosis spreading in form the several ventricles and the aqueduct, that as the lesions are disseminated through the cerebrospinal axis the disturbances are therefore, especially liable to affect systems which are extensive The areolar zones, the true areolar areas, and the perivascular sieve-like areas are secondary processes, the result and not the cause of the sclerotic areas Sites of predilection are probably related (1) to the vessels and (2) to areas in which much glia is normally present

10 **Spastic Paraplegia, Death Due to Diabetes Mellitus and Boils**—The case reported by Bramwell was carefully observed for seven years, most marked spastic paraplegia was the only condition present The patient was again and again examined in the hope of detecting some of the characteristic symptoms of disseminated sclerosis Such symptoms never developed, but postmortem examination showed the characteristic lesions in the spinal cord of disseminated sclerosis The amount of sugar passed per diem varied from *700 to 1 300* grains The patient died with symptoms of acetone poisoning

December 9 1916 II No 4867

30 Injuries of War A M Sheild—p 967 To be concluded
31 *Agglutinating Properties of Certain Serums against B Typhosus and B Enteritidis Gaertner (Delepine, 7160) T T O Farrell—p 970
32 Chronic Gonorrhea Cured by Electrolysis C Russ—p 977
33 Case of Bullet in Sphenoidal Sinuses, Removal Through Left Nostril H E Harris—p 978
34 Retained Placenta in Rudimentary Horn of Uterus M C S Lawrence—p 979
35 Case of Congenital Absence of Nails B O Neill—p 979

31 **Agglutinating Tests in B Typhosus**—Out of the 270 serums of inoculated men examined by O'Farrell, 87 1 per cent gave positive agglutination for *B typhosus* The serums of men inoculated twice give more positive reactions than men inoculated only once The presence of syphilis (as indicated by a positive Wassermann) does not affect the agglutinating power of a serum for *B typhosus* Out of 366 serums, consisting of both inoculated and noninoculated men who either had or were suspected of having syphilis, 19 6 per cent agglutinate *B enteritidis* Gaertner (Delepine, 7160) when a 1 in 25 dilution is used A much smaller percentage may agglutinate this bacillus up to a 1 in 250 dilution None of these serums were found to affect 7160 in a higher dilution Out of thirteen cases with a previous history of typhoid only three agglutinated 7160 These cases had had typhoid eight, ten and eighteen years, respectively, previous to the date of examination The ten cases not agglutinating 7160 had histories of typhoid four months to twenty-two years previously Any of the serums clumping 7160 which were examined for coagglutinins for paratyphosus A or B proved negative

35 **Congenital Absence of Nails**—O Neill's patient had no nails at all on the thumbs or fingers or great toes and only tiny fragments of nails on some of the other toes The nail beds were present on all the digits of the hands and feet and the fragments of nails found on some of the toes were placed round the edges of the nail beds or on the nail beds themselves The thumbs fingers and great toes had a hooded appearance at the extremities In the fingers and thumbs the nail bed had an upper paler part and a lower shining and more vascular part the latter corresponding to the lunette in the nail of a normal digit Two younger sisters aged 25 and 6 years, respectively were similarly afflicted The mother had the operation of avulsion performed on the nail of one of her great toes during the time when she was carrying the subject of this note

53 *Irresistible Desire to Sleep after Eating (La narcolepsie digestive) R Goiffon—p 95

48 **Glycuronuria with Liver Disease**—Roger enumerates the various factors liable to influence alimentary glycosuria, the greater or less absorbing power of the bowel, the eliminating power of the kidneys, and the power of sugar consumption by the tissues Induced alimentary glycosuria is thus unreliable as a test, but we have learned that sugar and glycogen aid in defending the organism against poisons In normal conditions there is enough glycogen on hand to combine with the poisons into compounds—conjugated glycuronic acids—which are comparatively harmless and are readily eliminated by the kidneys In normal conditions the urine contains about 0 04 gm glycuronic compounds to the liter Most of them are conjugated with phenol and indol The glycuronuria subsides during starvation along with the glycogen content of the liver On a milk diet it also subsides, at the same time there is less putrefaction in the intestines After a dose of 0 5 to 1 gm of camphor before starchy or sweetened food, intense glycuronuria follows if the liver is functioning properly With the Tollens and Rorive reaction it is easy to estimate and follow the proportions of glycuronic acid in the urine He gives the exact technic saying that the naphthoresorcin method is so sensitive that the reaction is distinct even with 0 002 gm in a liter of water, and shows up variations even of 0 01 per thousand

Among the clinical experiences related are the absolutely concordant findings with cirrhosis of the liver, and in 32 cases of jaundice from retention of bile Chronic nephritis and cerebral hemorrhage do not seem to modify the glycuronuria In 14 cases of heart disease, the glycuronuria was far below normal in the 7 severe cases with asystole In 3 other cases of asystole the glycuronuria was normal in one and this patient recovered The other 2 had no appreciable glycuronuria and both died Of the 40 pregnant women examined 65 per cent of the 20 with stomach trouble or albuminuria with edema showed complete absence of glycuronuria, 30 per cent had very little and only 5 per cent had very pronounced glycuronuria Of the 20 healthy women, all had a little glycuronuria and it was quite pronounced in 70 per cent These figures are startling as they show that the liver is suffering more or less in even mild pathologic cases They emphasize the instructive importance of tests to determine the conditions in regard to elimination of glycuronic acid as a routine procedure in pregnancy, when there is anything to suggest abnormal conditions The findings in pneumonia are suggestive also In short Roger declares, glycuronuria is to date the most practical index of the protecting power of the liver and the technic for gaging it is comparatively simple and is now ready to be adopted into general practice

The most sensitive method, albeit a little more complicated, is to add o 5 c c of urine in the centrifuge tube 0 2 of ammonia water (*ammoniaque*) and then 2 c c of the commercial solution of lead sub acetate The tube is filled up with distilled water containing 1 per cent ammonia water After moderate centrifuging the fluid is decanted and washed twice with the ammoniacal solution centrifuging each time Filtering may answer instead of centrifuging but it takes very much longer The precipitate thus purified is mixed with 5 c c distilled water and the whitish mass resulting is poured into a test tube and after this 0 5 c c of a 1 per cent alcoholic solution of naphtho resorcin The rinsings of the centrifuge tube with 5 c c pure hydrochloric acid e added and the test tube is placed in the boiling water bath for fifteen minutes It is then cooled in running water and agitated with 10 c c ether The tint is yellow or slightly tends to pink if there is no glycuronic acid present in the urine With a positive reaction, the ether turns violet the tint more or less pronounced This method i particularly instructive when the urine contains quantities of reducing substances This is readily recognized by heating with a little Fehling s solution The tint then becomes yellow brown or greenish

49 **Cancer of the Esophagus**—Sarmento relates that of the 716 cases of cancer in Mathieu's service, 1910-1915 fully 20 per cent were in the esophagus or cardia, and one in every 2 36 were in the middle third of the esophagus Of the total 172 cases, all but twenty-five of the patients were men The proportion of cancer cases was 716 to 8,397 patients in the

service during the six years in question The Roentgen findings in some typical cases are reproduced Progressive difficulty in swallowing is the most important and most constant sign of cancer of the esophagus The survival was never longer than twelve months after dysphagia appeared

50 **Spasmodic Closure of a Gastro-Enterostomy**—The gastro-enterostomy proved a success only part of the time At intervals it seemed to close up completely The operation had been done and the pylorus shut off to aid in curing an ulcer at the pylorus Zweig has reported a demonstrative case of the kind, cured by a sedative to relax the spasm In the case here reported by Urrutia the gastro-enterostomy closed up by the end of the first week, and the man vomited everything taken into the stomach A secondary operation was contemplated and the stomach was rinsed out morning and evening Sometimes the stomach was found empty, at other times it contained all that had been ingested since the last lavage or vomiting attack After failure of papaverin to relieve, belladonna three times a day, half an hour before meals arrested the spasms completely, and in the first three weeks of freedom from vomiting the man regained over 15 pounds Zweig encountered seven cases of this kind in twenty-seven patients after gastro enterostomy, but this is the first in Urrutia's sixty gastro-enterostomies followed to date In a number of them it was noticed during the operation that the stomach contracted spasmodically more than once while it was exposed

51 **Treatment of Hemorrhagic Rectocolitis**—There did not seem to be ulceration in the case reported, but the condition had grown so grave in the course of seventeen months that a fatal outcome seemed inevitable and cancer more than probable Persevering local treatment for seven months finally cured the patient, and disproved the assumption of malignant disease The treatment was by injection into the rectum of bismuth subgallate and zinc oxid The patient was a woman of 43 and the rebellious bloody diarrhea had induced much emaciation Only brief if any benefit had been derived from dietetic measures

53 **Imperious Desire to Sleep After Eating**—Narcolepsy is the term used by Gelineau to express a sudden imperious desire to sleep for a few moments or minutes, recurring more or less regularly Lhermite presented a report on this subject at a neurologic congress in 1910, with full bibliography Gelineau explained the narcolepsy as an autonomous neurosis, but others regard it merely as a symptom in various intoxications, etc Goiffon here emphasizes its import as a sign of indigestion He publishes a number of typical cases of this acute somnolency after eating even a small and light meal The desire to sleep comes on so suddenly and irresistibly that it constitutes an actual danger In one of his cases the man was chopping wood, and the irresistible desire to sleep came on him with such sudden force that the ax dropping from his relaxed hand, cut his foot seriously The slumber is actual sleep, not an epileptiform 'absence It lasts only a few minutes, fifteen is the average and on waking the persons feel refreshed There was always a history of stomach troubles in these cases but they were of a mild type mostly sensory motor disturbances with deficient gastric secretion Only four of his patients of this type had hyperchlorhydria and tardy pains All were thin and inclined to asthenia, but the correction of the abnormal conditions in the stomach supplemented with a little psychotherapy cured in every case In some of Gelineau s cases emotional stress brought on the narcolepsy but in Goiffon s cases the dyspepsia was evidently the exciting cause In one case a man with hyperchlorhydria had this sudden narcolepsy occur for the first time, it lasted for twenty minutes and when he roused he vomited quantities of blood, his first hematemesis

64 Trench Fever (Fievre des tranchees) R Morichau Beauchan—p 463

61 **Sorting Station**—Mignon discusses the arguments for and against having a special field hospital to classify and direct to specialist centers the wounded as they are brought in His final conclusion is that such an institution is not needed during periods of comparative calm, and it would not be useful even when the wounded are being brought to it in large numbers unless there are plenty of beds available, so the severely wounded could be kept and only the minor cases sifted out and sent to the rear

63 **To Hasten and Intensify Vaccine Immunization**—Camus has found that given a vaccine of a known strength and using exactly the same quantities we can count with precision that the results will be the same Changes in the quantity and in the activity of the virus bring differences in the vaccinal response He experimented with rabbits and tested the immunity by intravenous injection In ordinary times it is immaterial whether five days or ten days or longer are required to ensure immunization His experiments teach that when it is important to shorten the interval, the vaccine should be exceptionally active and it might be inoculated at several points He urges others to make practical tests of this in vaccinating children, comparing the interval before immunity to a second vaccination in children inoculated only once and those inoculated at six points

66 **Soap in Treatment of War Wounds**—Ratynski deplores that more use is not made of soap in cleansing wounds and in local treatment afterward His experience with it has been remarkably favorable as he describes in detail He uses 25 gm castile soap to the liter of water, or doubles this strength for the cleansing procedures For local treatment he applies it in a 20 per cent solution in which the compresses are dipped In his 1,500 dressings of the kind the results were at least equal to those of any other methods of treatment while the invariable absence of pain is a special advantage of the soap treatment

67 **Diagnosis of Death at the Dressing Station**—Satre relates that in many of the wounded and shell-shock cases

the men owe their lives to the persistence with which the physician kept up artificial respiration or other means to start the vital functions anew when the man wounded in the head or spinal cord or asphyxiated by gases seemed dead beyond redemption In some cases resuscitation was realized after four or even six hours of the continuous application of such measures Subcutaneous injection of 10 c c of a 20 per cent solution of fluorescein can be done without interrupting the artificial respiration or rhythmic traction of the tongue [The fluorescein has to be dissolved in a dilute alkaline solution] If there is still the slightest circulation, the stain diffuses readily and is particularly evident in the conjunctiva 'The eyeball looks like an emerald in its orbit" This encourages all concerned to keep up the life-saving measures, when without it the aids are inclined to think that not only the efforts are being wasted but that the dead body is being profaned It is better to treat a dead man as if there was still life than to let one live man be left for dead when he might have been saved Another test for certain death is the change of the alkaline reaction of the spleen and liver to an acid reaction This occurs half an hour after death and persists a long time A fine puncture needle is pushed into the spleen or liver, the scrap of visceral pulp thus obtained is spread on blue litmus paper drawing it apart from blood that may come with it The pink tint is very pronounced two hours after death Before this it may be necessary to lift up the scrap of pulp to see the change in tint under it If this characteristic color reaction does not occur within five minutes the spark of life is not extinct The question of real or apparent death comes up again and again on the firing line as men perfectly sound a few minutes before until the explosion of a shell nearby are brought in inanimate, sometimes without any signs of physical injury

68 **Suprarenal Insufficiency in Malaria**—Paisseau and *Lemaire affirm that the suprarenals are responsible for the* attacks of coma the algid phase and the choleriform symptoms in pernicious malaria Necropsy has revealed acute degeneration or acute hemorrhagic disease in the suprarenals in their fatal cases of pernicious malaria The knowledge of this acute or subacute pathologic state of the suprarenals explains many features of the clinical picture of malaria especially the changes in the arterial tension the asthenia, the lumbar and abdominal pains the vomiting and diarrhea The conclusion is inevitable that epinephrin should take its place next to quinin in treatment of severe forms of malaria

69 **The Initial Stimulating Phase of Atropin Action**—Petzetakis reports clinical and experimental data which confirm that atropin has first of all a stimulating action During this initial phase it acts on the vagus nerve and the effect is manifest in extrasystoles and dissociated functioning of sinus and auricle and of the auricle and ventricle Testing the direct and reflex excitability of the vagus at different times reveals the initial period of hyperexcitability of the vagus manifested by the change in the heart rhythm and tendency to irregularity

Medizinische Klinik, Berlin

October 29 1916 XII No 44 pp 1143 1166

74 *Diagnosis of Typhus (Ueber den augenblicklichen Stand der mikrobiologischen Fleckfieberdiagnose) R Otto—p 1143
75 *Advice and Treatment of Nursing Women (Ueber fehlerhafte Behandlung stillender Mutter) A H Kettner—p 1147
76 Analysis of the Functions of the Hand M Cohn—p 1151
77 Splints Permitting Joint Functioning (Gelenkmobilisationsschienen nach Dr Schede) Neumeister—p 1153

74 **Diagnosis of Typhus**—Otto discusses the present status of the microbiologic differential diagnosis of typhus, saying that microscopic examination of lice from the patient is a simple and reliable measure, as also the Weil-Felix reaction He gives three illustrations of the microscopic findings in a typhus louse, showing the rickettsia in the epithelium of the louse intestine The only absolutely conclusive test is the artificial infection of normal lice, but this is too complicated a procedure for common use The finding of rickettsias in a number of lice is practically adequate for the diagnosis, without waiting for their proliferation Louse smear preparations show up the rickettsias instructively even though we are not certain as to their nature Otto mentions that the Wassermann reaction is sometimes positive in typhus, quite often if active serum is used It is not specific as it occurs with both syphilitic and typhus organs The precipitin reaction was always negative in his experience The Widal agglutination test is instructive only when persistingly negative The Weil-Felix agglutination seems to be conclusive He got agglutination with it at 1 50 up to 1 1600 with typhus patients but never with other patients, even at 1 20

75 **Advice to Nursing Women**—Kettner denounces a number of prevailing prejudices and customs in regard to lactation saying that the woman should merely be advised to live eat and drink what she wishes as in health before she became pregnant only taking a little larger quantities as she is now living for two" At first it may be advisable to take smaller and more frequent meals, but after she is up and about the ordinary meals may be resumed He advocates considerable exercise especially in the open air, light sports and gardening are particularly beneficial and not used often enough by nursing women About 1 5 liter of fluid daily is enough including 1 liter of milk and the rest in mild beer or, better yet, pure water During the summer, water should be *taken more freely not quenching the thirst with gruels, teas,* etc but merely with water This applies to the infants also

He explains that various factors combine to induce constipation after delivery It may be regarded as physiologic and the giving of purgatives only enhances the tendency after the immediate action is over They have the disadvantage further that they attract the blood into the abdomen drawing it away from the breast, where it is needed most The purgative checks or arrests completely the work of milk production in the mammary glands, and this is the opposite of what should be done A dose of castor oil or other purge may turn the scale against the normal development of lactation, especially if the child does not take hold well This is most likely with the first child and midwives and attendants often find it less trouble to give up the attempt to have the child fed at the breast When this occurs at the first childbirth, the woman assumes as a matter of course that she is unable to nurse any of her later children "At the same time" Kettner continues 'these infants who take hold weakly are the very ones that need prolonged breast feeding most imperatively on account of their constitutional weakness, and the war has increased the numbers of such" The bowels can be moved with enemas, but chemical purgation interferes with the development of the mammary gland function which may be under way days before delivery If we have chronic constipation to combat, then the bowels should be regulated with mechanically acting substances rather than the chemical purges Regulating the diet and keeping up these measures usually brings success in time while it does not interfere with lactation

Kettner comments further on the efforts being made at various infants' hospitals etc, to train young girls in the care of babies, saying that many mothers shrink from letting their daughters take the course from fear of contagion This drawback can be overcome by decentralizing the work Instead of large institutions organizing a number of smaller establishments, like the two already at work at Charlottenburg affiliated with the infant welfare stations Each has only a few beds, conditions thus approximating better those in the home and enabling the young girls to be trained practically in the duties of motherhood

In conclusion he insists that not enough care is spent on preparing the nipples for nursing Inappropriate clothing and nonuse render them soft, and they have to be toughened Air and water are what is required The clothing should be loose and light over the breasts, they should be given air baths during the day, and, several times during the day at least on rising and retiring, the whole breast should be doused with cold water If the nipples are particularly tender they can be dabbed in the morning with a little alcohol to harden them and at night a little glycerin or tannin-glycerin applied to make them pliable

At the first sign of smarting, indicating a crack in the nipple, it should be treated with alcohol without the slightest delay, or touched with a silver nitrate pencil Salves and moisture undo what has been accomplished in toughening the nipple The main thing however, is that the child must be allowed to nurse the nipple as before, even if it does hurt If the woman is very sensitive, a nipple cap can be used and in extreme cases a local anesthetic salve may be applied half an hour before the nursing The breast must be emptied as completely as the other Even if phlegmonous mastitis develops, cases are known in which the phlegmon opened into a lacteal gland and the contents were taken by the child in its milk without harm There is no need for such anxiety about the child, when there is mastitis, as is often felt Even if operative treatment is required we should not dress the breast so nursing is impossible or warn the mother against it The dressings should leave the nipple exposed All antiseptics should be scrupulously avoided on account of the infant s sensitive sense of smell The mother should be persuaded to give each breast in turn to the child as usual It generally nurses as if nothing was wrong, or any distaste at first is soon overcome It is remarkable that while stasis hyperemia is directly beneficial in phlegmonous processes elsewhere, stasis of milk has the opposite effect and prompt aggravation ensues In a recent case the surgeon protested against treatment on these principles but finally yielded and applied the dressing so the child could nurse freely Instead of the three weeks' course he had anticipated, the process had completely healed in ten days, lactation had not been interfered with and the weakly child had its natural food throughout and for a long time afterward while the mother s period of suffering had been materially abbreviated

Monatsschrift fur Kinderheilkunde, Berlin

September 18 1916 XIV No 2 pp 123 170

78 *Composition of Gruels Commonly Used in Infant Feeding (Ueber die Zusammensetzung der in der Sauglingsernahrung gebrauchlichen Schleime) H Bratke —p 123

79 *Severe Epidemic of Measles (Klinische Beobachtungen uber Erscheinung und Nachwirkung einer schweren Masernepidemie 1915 in Gottingen) L Lande —p 143

80 Are Infants Born with Much Vernix Caseosa Particularly Liable to Skin Disease Later? (Vernix caseosa und Erythrodermie) K Stolte —p 168

78 Gruels in Infant Feeding—Bratke refers to very thin gruels made by cooking a tablespoonful of oatmeal or other grain in a pint of water filling up the water to this measure as it evaporates He reviews the literature on the subject and describes his own tests and research to determine with precision the various chemical elements in gruel The unmistakable superiority of oatmeal barley or rice gruel seems to be due he thinks to the better utilization of the starch on account of the long cooking If flour soups were cooked as long in comparison, they would be utilized equally well

79 Severe Epidemic of Measles—Lande relates that between April and November last year there were 192 children with measles or its sequels at the Gottingen children s clinic and policlinic All ages were represented, including 4 infants between 3 and 6 months old but over two thirds were between 6 months and 3 years old Ten per cent of the 192 children died and only 27 were not left with some serious complication or sequel Several cases developed in the hospital in infants kept in adjoining cubicles of the L F Meyer box system confirming the view that the box system does not protect against measles Pneumonia and influenza were prevalent during the epidemic, which explains the frequency of complications on the part of the lungs or bronchi Just as in malignant scarlet fever, the fatalities seemed to be due mainly to mixed infection for which the measles prepares an exceptionally favorable field Thirty-one of the children developed some infectious disease or it had been already installed, including whooping cough in 12 cases in 45 there was pneumonia with some other respiratory affection in 6, diarrhea during the prodromal period in 11, throughout the disease in 22 resembling dysentery in an additional 5, and actual dysentery in 2 There was otitis media in 26 and conjunctivitis, sometimes with ulcer of the cornea in 9, hemorrhagic nephritis in 3 meningitis in 3 and sepsis in 13 The measles children in the homes even of the well to do were found in dark unventilated rooms as the popular prejudice demands protection against light and air for measles The exact ear findings in a number of cases early in the disease are given in tabulated form Many of the previously robust children were left pale, languid and irritable by their measles not only their physical but their intellectual development showing impairment Treatment was symptomatic with care for adequate intake of fluid and food, stimulating tepid sponges, warm baths with dash of cool water or mustard bath, stimulating respiration and circulation and preventing the child from sinking into dangerous somnolency, with efforts to ward off mixed infection by air, light and cleanliness In 92 of the 192 cases described the children were first brought to the hospital after the actual measles had run its course In one such case a formerly healthy boy of 3 died six weeks after the measles from a combination of pneumonia pleurisy, pericarditis and nephritis another somewhat younger died seven months after the measles from pneumonia which had run a protracted course and he succumbed to another attack

81 The Carbon Arc Light in Treatment of Tuberculosis of the Skin and Mucosa—Spitzer reports experiences at Vienna which confirm the statements of A Reyn of Copenhagen in regard to the therapeutic efficacy of exposure to the carbon arc light The lamp used in the Lupus Sanitarium of which he has charge has an 80 ampere current, 60 volts, while Reyn worked only with 7 and 20 ampere currents The stronger light enables a number of patients to be treated at once

Spitzer was amazed at the way in which acute tuberculous ulcerations in the mouth and also the chronic granulating form healed completely in a month or two He had six cases of these types, including one in which the ulcerations had burrowed deep into the tongue, with extensive ulceration in the lips and extreme cachexia The arc light seems to be the sovereign cure for such cases The quartz light gave better results in joint cases He gave daily exposures of an hour each, beginning with fifteen minutes and increasing by fifteen minutes to an hour by the fourth day, and continuing with hour sittings There seems to be a favorable general action in addition to the local effect He aims to induce an erythem with casting off of the epidermis and continuous exfoliation for the first two weeks

82 **Disturbances in Vision with Nephritis**—The conclusions from the clinical and functional study of nephritis here reported are to the effect that albuminuric neuroretinitis seems to be causally related to that disturbance of kidney functioning which leads to azotemia It is very seldom found with acute, diffuse glomerular nephritis, but occurs in about 50 per cent of the cases of malignant sclerosis in the kidneys and also in chronic glomerular nephritis in the stage of insufficiency It is thus shown to be connected with the glomeruli It aids in differentiating early stages of malignant sclerosis of the kidneys from the benign form In chronic cases it indicates a fatal outcome in two years at longest Eclampsic amaurosis is encountered as part of the syndrome of eclampsic uremia The fundus is normal except for the occasionally noted edema of the papilla The prognosis is generally favorable In exceptional cases it may be combined with albuminuric neuroretinitis Lumbar puncture is recommended in treatment

Pseudo-uremic disturbances in the visual apparatus are encountered exclusively with sclerosis of the kidney They are generally briefly transient and are probably traceable to arteriosclerosis and spasm of the cerebral arteries Among his 51 cases of acute diffuse glomerular nephritis two of the men had albuminuric neuroretinitis and although the kidney disease soon retrogressed the neuroretinitis persisted unmodified for the months the men were under observation One of the men had besides acute eclampsic uremia with transient amaurosis Among the total 150 cases of acute diffuse glomerular nephritis 25 of the men died during the uremic stage, in the other 125 cases the men recovered or the disease passed into a chronic phase In 74 in this group there were no signs of azotemia at any time, and no tendency to albuminuric neuroretinitis was ever detected in any in this group, nor in 48 cases of acute and chronic nephritis, 15 of focal nephritis, and 20 of chronic diffuse glomerular nephritis in the second phase but it was pronounced in 15 per cent of the 20 cases in the third stage also in 52 8 per cent of 36 cases of malignant sclerosis of the kidneys

86 **Agglutination of More than One Infectious Germ**—Baerthlein relates instances of para agglutination of the saprophytic germs with the cholera vibrio, typhoid or paratyphoid, Flexner or Y dysentery bacilli in various combinations In one case, for example there was agglutination for cholera at 1 50 for typhoid at 1 200 and for dysentery bacilli at 1 100, with marked agglutination of certain bacteria found which are not usually regarded as pathogenic With a syndrome suggesting dysentery for instance, the only germs that could be cultivated were some resembling the colon bacillus, but there was agglutination with these bacilli at 1 2,000 when tested with Flexner dysentery bacilli In the blood serum there was clumping of the latter and also of the colon bacilli at 1 400 The cure was soon complete under treatment as for dysentery He emphasizes the importance of this para-agglutination as an aid in the diagnosis of typhoid and of dysentery in particular It differs from coagglutination in that the latter is a group reaction from receptors naturally and permanently allied, while with para-agglutination the common receptors are only a transiently acquired property It seems likely that the colon and coccus strains in question adsorb the agglutinating substances produced by the dysentery or other bacilli Baerthlein has been able to induce para-agglutination in vitro with ordinary colon bacilli kept for a time in contact with killed cultures of cholera, typhoid, paratyphoid, or dysentery germs

89 **Relapsing Fever and Lice**—Topfer states that he found the spirochetes of relapsing fever proliferating in lice after they had bitten relapsing-fever patients The spirochetes retained their shape, motility, virulence and staining properties, and no special developmental phases were noted Infection does not seem to be transmitted by the bite of the louse but the spirochetes released by crushing of the louse get into the lesions made by scratching

91 **Diagnosis of Gas Gangrene**—It has been proposed to detect incipient gas gangrene by determining the specific gravity of an excised scrap of muscle Biermann merely strikes the suspected region with the thinnest pincers available, held as a tuning fork is held. When there is accumulated gas even in the depths of the muscle below, there is a dull note like the cracked-pot sound on percussion of a tuberculous cavity in the lung The exact area involved can be outlined in this way The odor of a gas phlegmon is so unmistakable that there is little danger of confusing the findings with a simple emphysema in the skin

95 **To Keep Sharp Instruments from Rusting**—After thorough mechanical cleansing, Frank stands the instrument in a bottle filled with alcohol containing 5 or 10 per cent soap spirit The addition of the tincture of soap prevents rusting An illustration is given of a Pravaz syringe thus kept ready for use It is filled with the fluid, and stood upright over a bottle, the needle projecting nearly to the bottom of the bottle, and the handle held between two nails driven into the wall

101 Fistula from Gravity Abscess Persisting for Two Years after Intramuscular Injection of Salvarsan (Eigentümliche Folgen einer intramuskularen Salvarsaninjektion) K Polland—p 1339

96 **Typhus**—This monograph on typhus and lice presents the present sum of our knowledge on the subject Fonyo states that the body louse dies in five days if it is unable to feed on human blood during that time The nits hatch out in two or three days and if the young lice are unable to get blood they also die within five days Consequently closing a lice-infected building for two or three weeks all human beings keeping away from it kills off all the lice young and old The outer covering of the louse is extremely resistant to water, acids and alkali, but its respiratory apparatus is exceptionally sensitive to gases and fumes and they pass thence into the protoplasm This explains the effectual action on them of mercurial salves, as they breathe the fumes Ethereal oils, benzin and 10 or 25 per cent water of ammonia (*Immonial*) have also been found effectual in warding them off or destroying them Lice are so prolific that Leuwenhoek has estimated that the progeny of a single louse can within eight weeks total 5 000 Fonyo emphasizes further that to get rid of vermin all the persons involved must be rid of vermin all at practically the same time If even one person is overlooked, the success of the whole measure is compromised

97 **Behavior of the Mononuclears in Malaria**—Zweig and Matko have been making a comprehensive study of the modifications in the blood picture under the influence of malaria with and without quinin They describe them in detail, calling attention in particular to the segmentation of the mononuclears in the blood stream

98 **Parenteral Injection of Protein in Treatment of Trachoma and Other Eye Diseases**—Friedlander made intra-

gluteal injections of 10 c c milk in forty-two cases of trachoma, all of the severer type The effect was surprisingly good A number of particularly demonstrative cases are reported in detail, as also some of rebellious catarrhal ophthalmia which promptly subsided under one or two of the injections four days apart The interval was never less than forty-eight hours, he always waited for the temperature to return to normal In some of the cases a long previous course of office treatment had given no relief but the earning capacity was restored the day after a single injection at 5 p m One hour afterward the temperature was 36 6 C, at four hours 36 8, at seven hours, 37, at 3 a m 37 5, at 6 a m 36 1, and at 4 p m 36 2 C In conclusion he remarks that the epidemic of trachoma was thus stamped out so promptly and effectually that he has had no opportunity since to apply the method

100 **Significance of the Facialis Phenomenon**—Pulay found Chvostek's sign pronounced in 24 6 per cent of 211 male adults in the hospital in his charge, and, with scarcely any exceptions, in every one of the positive cases there was macroscopic evidence of tonsil disease The intensity of the facialis phenomenon seemed to be proportionate to the severity of the tonsil lesions With a unilateral Chvostek sign the tonsil on that side was the one affected These findings testify that the facialis phenomenon must be regarded as almost invariably a sign pointing to pathologic conditions in one or both tonsils The findings in sixty-three cases are tabulated Pulay adds that the presence of the Chvostek sign early in pulmonary tuberculosis is thus explained, and it suggests that prompt treatment of diseased tonsils may prove an important aid in treatment in all forms of acute and chronic disease Plugs in the tonsils, he continues may not set up any appreciable local inflammation and yet they may be responsible for lassitude, drowsiness, slight rise in temperature and depression—a condition often labeled neurasthenia from ignorance of the tonsil plugs He adds that there was probably unsuspected tonsil disease in the cases of tetany in which the Chvostek sign has been recorded

123 *The Parathyroid Glands (Epitheellichaampjes) H A Vermeulen —p 1779
124 *Phagocytosis of Red Corpuscles by Polynuclear Leukocytes (Phagocytose van erythrocyten door polynucleaire leucocyten) L Schaap and J W Wolff —p 1789

122 **Origin of Hallux Valgus**—Milo has had casts taken of the feet in a dozen cases of hallux valgus, and study of them has convinced him that the generally prevailing views as to the origin of this trouble are erroneous It is in reality the inevitable consequence of loss of the transverse elasticity of the fore part of the foot When the fore part of the foot has lost its transverse resilience from insufficiency of the transverse muscle, it may entail metatarsal neuralgia, Morton's disease ostitis, etc and dislocation of the great toe—hallux valgus—is practically inevitable He gives an illustration of the cast from the foot of one young woman Her feet had been normal until a tuberculous process developed in the middle metatarsal bone This was operated on successfully but the transversus pedis muscle was severed Although the foot seems clinically normal, yet hallux valgus followed within three months He emphasizes the necessity for detecting early this spreading of the foot and counteracting it, thus warding off secondary hallux valgus

123 **The Parathyroid Glands**—Vermeulen is a professor in the Veterinary College at Utrecht He here describes and illustrates the parathyroids as found in domestic animals, and reviews the literature on the subject To obtain parathyroids for therapeutic purposes he has found that for various reasons the sheep seems to be the best available animal The parathyroids in them are large and comparatively accessible after removal of the salivary glands The stroke to slaughter the animal should be made a little lower than is customary, to avoid injury of the parathyroids and the skin should be removed with care The sheep should also be over two years old This can be told from the teeth, as he describes in detail The parathyroids in hens are also available, they are small but compact and accessible The parathyroids offered now on the market are not always reliable, and his analysis of the anatomic conditions readily explains the mistakes liable to be made in removing the parathyroids

124 **Phagocytosis of Red Corpuscles by Polynuclear Leukocytes**—The experiments described were made with sheep or rabbit red corpuscles injected into the peritoneum of guinea-pigs The abdominal fluid was withdrawn by puncture at hour intervals afterward The red corpuscles were found incorporated in the polynuclear leukocytes, which had accumulated in large numbers in the peritoneum By the end of the fifth hour the large mononuclears take up the task

128 *Means to Promote Lactation (Några erfarenheter angående digivning) H Ernberg—p 1636

125 **Diagnostic Findings on Repeated Skin Tuberculin Tests**—Lindberg has applied repeated skin tuberculin tests to 129 children in the hospital and sanatorium with which he is connected The ages ranged from 1 to 12 years The tuberculin skin test was applied to each arm and again after an interval of a week The reaction twenty-four hours after the test and a week later, was measured in both the axial and transverse diameters When neither diameter was over 5 mm the reaction was recorded as negative The findings are tabulated for the entire number, with further details as to the general condition etc Of the 129 children 33 3 per cent showed a much more pronounced response at the second double test than at the first In 60 per cent the response was weaker than at the first, in 6 7 per cent there was but slight difference

Classifying the cases in three groups as certain active tuberculosis, probable tuberculosis and the nontuberculous, he found this intensification of the reaction, or positive sensitization, *in only* 5 3 per cent of the 36 cases in the first group, in 28 5 per cent of 16 in the probable group, and in 78 per cent of the 18 nontuberculous These data confirm the assumption of a connection between this sensitization and the phases of tuberculosis, in that as a rule the response to the second application of the test is weaker when there is active tuberculosis, and stronger when it is latent Of the total 129 children, 75 had given a positive response when first tested In Bessau-Schwenke's research along similar lines 129 of 153 children had responded with a positive reaction in the Pirquet test The proportional findings with the repeated tests harmonized in both series confirming the reliability of the above deductions In a further series Lindberg obtained the positive sensitization in only 15 per cent of 20 children with manifest tuberculous processes in bones or joints A fourth table gives the findings in 15 supposedly healthy children and 15 healthy adults

The results of the whole research testify that with inactive tuberculosis the response to the repetition of the tuberculin skin test is more pronounced than at the first test, while the reverse is the rule with active tuberculosis The attenuation of the response to a second application of the test has thus a favorable instead of an unfavorable significance He found it most instructive to record the sum of the diameters of the reaction, including both the twenty-four hour and one week measurements

127 **Diagnostic Import of Abnormal Conjugated Movements of the Eyes**—Antoni reports in detail an instructive case of left hemiplegia with conjugated deviation of head and eyes to the right positive Wassermann reaction and typical response to the Barany caloric and other tests, all testifying to an extensive lesion in one hemisphere The phenomena observed confirm the assumption that an antagonistic inhibiting impulse proceeds from the center on the opposite side, and this persists after destruction of one center This explains the different behavior during and outside of coma, according as the brain is capable of the inhibiting action or not As consciousness is regained, the inhibiting function of the intact center is restored Antoni's research during general anesthesia has apparently disproved certain current assumptions in regard to vestibular reflexes, as he describes, and also in regard to a possible subcortical center and the so-called syndrome of Deiter s nucleus

128 **To Promote Lactation**—Ernberg remarks that nowhere in practical medicine is prophylaxis of such vital importance as in pediatrics and means to ensure breast milk for the child take the lead in this respect When the mother does not yield enough milk in the first five or six days this may be because the efferent passages are not fully permeable The amount of milk is also liable to dwindle during the third or fourth week, probably because the woman is resuming her usual household tasks before she is quite strong enough In all these cases the milk secretion has to be stimulated, and the natural stimulus for this is the sucking of the child The oftener it sucks the better the breast responds, but it must suck vigorously to be effectual In such cases he advises letting another babe nurse at the same time or at alternate times with the mother's own babe It may be necessary for this to have the woman go to some hospital or asylum where other babies are available By this means he has restored lactation even when it had been suspended for some time, having the breast nursed eight or ten times a day He gives the charts from four such cases In one after three weeks of nursing and two weeks of exclusive bottle feeding, ample lactation was restored in three weeks In another, after four breast weeks and five bottle weeks, it took seven weeks for ample lactation In the other cases there had been no breast feeding at all but after five or six weeks of bottle feeding the breast milk was gradually brought up to 600 gm in four weeks in one case and to over 1,000 gm in nine weeks in the other Three were primiparae He supplements the insufficient meal with artificial food weighing the infant after each breast feeding and giving enough of the bottle food to bring the total up to the desired amount As the mother is tranquilized by seeing that the child gets enough nourishment, this peace of mind has a further favorable influence on the lactation, and the amounts of supplementary artificial food required grow less and less

VACCINE THERAPY

ITS POSSIBILITIES AND LIMITATIONS *

DAVID JOHN DAVIS, MD
CHICAGO

A discussion of the possibilities and limitations of any topic involves more or less prediction In science it is dangerous to predict and especially is this so just now concerning the subject at hand, because we are in the midst of a revolution in methods and in interpretations as applied to this field It is with reluctance, therefore, that I attempt to present this subject, because I feel it cannot be done adequately at this time

After an attack of many infectious and contagious diseases, such as typhoid fever, smallpox, measles, scarlet fever, the body becomes for a long time highly resistant to the given disease, but not to any other disease The conception of specificity is here clear and definite

Many years ago Jenner found that smallpox in the modified and relatively harmless form of cowpox could be given to human beings and that they were then almost as resistant to smallpox as if they had had the disease

Pasteur, years later, showed that by injecting into animals certain modified living viruses (chicken cholera and anthrax) the animals then became resistant to natural infection and also to experimental infection with that germ This was true, however, of certain viruses only The injection of the virus of many other diseases did not so protect against subsequent infection

Later, Pasteur in his great work on rabies took advantage of the long incubation period in this disease and by the early injection of the modified virus contained in the spinal cord of infected rabbits was able to protect animals and man against the fatal outcome sure to follow in case symptoms once appeared This method, it is important to note, is in reality protective and not curative, because it is not effective if begun late or after the first symptoms have set in

Based on such experimental and clinical facts, which accumulated rapidly following the work of Pasteur, animals and man were given dead or modified living germs for protection in a variety of diseases Up to the present time this method has been used with marked success in man in typhoid fever and with some, but less definite success in plague and in cholera In animals, in symptomatic anthrax, swine erysipelas and rinderpest, marked success has been attained

For certain few diseases, then, the prophylactic use of specific vaccines has been thus far successful in both animals and man, but in the great majority of infections it has not been successful to any appreciable degree I wish to emphasize this point because it is in prophylaxis that we have the most favorable conditions possible, according to our fundamental principles of immunity, for the action of vaccines However, the marked success that has attended their use in such diseases as above enumerated establishes a practical and rational basis for their possible value in all infections Whether or not they will be efficacious in a given disease will of course have to be determined in each instance

I have referred to the above facts concerning prophylaxis because of their bearing on the curative use of vaccines A priori, on the basis of immunity principles, we could hardly expect to obtain better or even as good results when the virus is introduced during the course of the disease as when introduced previously What are the facts?

It was early observed that vaccination with cowpox virus during or after the onset of smallpox had no effect on the course of the disease Pasteur was well aware of the possibilities of a curative therapy as well as of a prophylactic one, but he reports no results of importance along curative lines Even to this day it is interesting to note that in the domain of animal diseases, which have been so fertile in furnishing valuable data for prophylactic therapy, there are no natural diseases known in which vaccines for curative purposes have been of any appreciable value Indeed, there is empirical evidence that vaccination just before or during an attack of a disease may do harm Veterinarians are careful not to expose cattle to infection soon after they have received prophylactic anthrax vaccine

Koch s work on tuberculosis in 1890 was perhaps the first serious attempt to apply vaccine therapy to the human and it was, as we all know, a failure at that time Scores of attempts with almost every imaginable modification of the bacillus, including extracts and bodies, have since been made Biggs states that treatment with tuberculin on the whole is being gradually given up in this country This is after a trial of twenty-five years It should not be understood from this statement that such treatment has no virtue whatever Trudeau's results would seem to indicate that when used discriminately tuberculin has some value perhaps in immunizing against the toxin A curative vaccine against the bacillus has, however, not been found

Fraenkel in 1893 used subcutaneously dead typhoid bacilli in the treatment of typhoid fever, with what he considered good results Rumpf shortly after claimed as good results when pyocyaneus bacilli were used in typhoid, thus very early questioning the specificity of vaccine treatment In recent years many reports have appeared dealing with this subject, the results being somewhat conflicting Beginning with the use of intravenous injections by Ichikawa in 1912 and by Gay and Chickering soon after, the treatment of typhoid, on account of termination by crisis in a considerable proportion of cases (30 to 40 per cent) thus treated, has excited much interest

---

* From the Department of Experimental Medicine University of Illinois

Read before the Section on Laryngology, Otology and Rhinology at the Sixty-Seventh Annual Session of the American Medical Association Detroit June 1916

Wright in 1902 inaugurated a new era in the use of vaccines by his discovery of opsonins This subject is so well known I will not enter into detail As contrasted with Koch's and Fraenkel's work, it attempted to place the use of bacteria and their products in the treatment of disease on a rational basis, controlled by a carefully determined standard, the opsonic index According to Wright, vaccines were suitable in certain subacute and chronic infections, the object being to stimulate the protective agencies of the body in order to rid it of localized and perhaps more or less protected foci Acute infections were not considered suitable for the use of vaccines, though it should be stated that from time to time reports appeared indicating that good results were occasionally obtained in acute cases Such results were not altogether in harmony with Wright's theoretical conceptions, because in severe acute infections the defenses of the body were considered already overwhelmed and vaccines merely added to this toxemia

Wright's work has been based on the principle of specificity, as was nearly all the work on this subject before his time It is interesting here to note how thoroughly this principle has dominated the thought of men since the beginning of the bacteriologic era The idea of specificity rests on an absolutely secure basis of clinical and experimental facts Yet it is perhaps not an overstatement to say that for many workers it has become a dogma Wherever the principle seemed to apply it was not thought necessary even to use controls in the observations So in the therapeutic application of vaccines, if good results were obtained, it was taken for granted that this was dependent on the specific effect of the vaccine and no thought was given to the possibility of other vaccines or substances producing the same effect This was due, I think, largely to the very indefinite results obtained by the subcutaneous use of vaccines in many diseases For since the intravenous use of vaccines and other products, decidedly more definite results are possible and control observations with numerous substances can more readily be made

Following the work of Wright, careful and scientific as it was, there occurred a flood of commercialism in connection with the preparation of vaccines and bacterial products of all kinds Apparently it matters little in this age what the therapeutic agent may be, if it is possible to commercialize it, this will be done The abuse of these products has been discussed so well and so recently by Pearce, Theobald Smith, Hektoen, Billings and others that I will not dwell longer on this point

Scattered throughout the literature are the reports of more or less isolated observations that in the treatment of infections, both acute and chronic, good results have followed the use of nonspecific substances Though many of these reports are quite definite, indeed some decidedly more so than those obtained by specific therapy, since they did not appear to be in keeping with the dominating conception of specificity, they were regarded with skepticism or indifference This subject has very recently been thoroughly developed and the specific facts stated by Jobling and Petersen[1] The problem largely centers around the toxic effect of colloidal substances, especially the foreign proteins, on injection into the body

The favorable results first reported by Kraus, Ichikawa and others by the intravenous injection of typhoid vaccine in typhoid fever were soon followed by the further reports of Kraus, of Luedke[2] and of J L Miller[3] that equally good results could be obtained with other substances, such as colon vaccine or even with solutions of proteins, albumose, etc , in this infection Mueller and Weiss[4] have obtained striking results in arthritis, especially gonorrheal arthritis, by the intragluteal injection of sterile milk and of sodium nucleinate, both of which substances cause a marked reaction Smith[5] calls attention to the value of an anaphylactic reaction, in gonococcus infections obtained with horse serum, normal or antigonococcic, it matters not, provided the allergic phenomenon is manifested Miller and Lusk[6] report striking results in acute, subacute and chronic arthritic conditions of various types by intravenous injections of typhoid vaccines and proteose

In our laboratory Culver, engaged recently in this work, reports that in the treatment of gonorrhea and its complications, especially arthritis and epididymitis, with the intravenous injection of bacterial suspensions, there seems to be no specific reaction when gonococci are used as compared with other organisms The results have been very pronounced in most cases, marked relief following a single injection The suddenness of the reaction and the severity as characterized by chill, high temperature and leukocytosis are more marked following the injection of meningococci than following either gonococci or staphylococci The improvement seems to be in proportion to the temperature and leukocytic reactions As to recurrence of the infections, nothing can be said at present as sufficient time has not yet elapsed

Mathers,[7] working especially on lobar pneumonia and erysipelas, reports that these infections have been treated during the acute stage by intravenous injections of various vaccines and protein solutions Suspensions of typhoid bacilli, pneumococci, staphylococci and streptococci have been used, as well as normal horse serum, diphtheria antitoxin and various protein solutions, both animal and vegetable All of these substances, when used in sufficient dosage, may give rise to a characteristic febrile and leukocytic reaction which in some instances was followed by a temporary clinical improvement No evidence has been gained, however, which would indicate that the specific vaccine in these diseases excels in any way the nonspecific antigen Mathers infers from his experience with erysipelas and pneumonia that the therapeutic results from this method of treatment do not warrant the general application of this method He has also observed that citrated human blood produces a reaction similar to that described above when injected intravenously in amounts usually advised in transfusions.

[7] Unpublished data

Since these very striking results have been obtained by the use of nonspecific protein substances, the specificity of treatment with serums in pneumonia and other infections and with vaccines, especially in typhoid, as reported by Gay, and in the many other diseases in which apparently good results have been obtained, may be called into question.

My own experience with vaccines, which began in 1904, has included a variety of infections, both acute and chronic. I have observed in certain cases, especially arthritic cases, and also in some colon infections, definite reactions, with chill, fever, leukocytes, etc., followed by a striking improvement. This experience, I think, has been a common one especially by those who have used large doses as well as small doses of vaccine. Naturally, the interpretation usually given to such reactions has been that they were specific responses on the part of the body to its autogenous virus. In the light of newer facts we are inclined now to view such reactions as probably nonspecific and of the same nature as those following injection of any foreign protein.

One difficulty in vaccine therapy has been to explain the good effects sometimes seen in the treatment of acute infections with vaccines. Wright himself and many other conscientious workers report such instances. As stated above, on the basis of the opsonic theory of Wright, this mode of treatment of acute infections was not a rational one and indeed was contraindicated. We may now believe that such favorable results were no doubt due to the nonspecific reaction caused by the bacterial protein.

At the present moment the facts would seem to indicate that the nonspecific substances referred to are able to do almost everything the specific vaccines have done in the cure of disease. In other words, the curative effects of vaccines reported heretofore may be explained by the action of the nonspecific substances in the vaccine rather than by its specific factors.

Jobling and Peterson,[1] in their analysis of the mechanism of the action of nonspecific therapy, call attention to a number of factors involved in this process. Selective stimulation of the hematopoietic tissues occurs, which results in flooding the body with antibodies which are specific, but the stimulus may be nonspecific. Hyperpyrexia and leukocytosis, emphasized especially by Gay and his associates in recovery from typhoid by this form of therapy, and the mobilization of serum protease and lipase, with an ultimate rise in the antiferment titer of the serum following injection of various foreign substances, are considered significant processes. These processes, they suggest, are dependent on certain changes resulting in the state of increased dispersion of colloids affecting both the serum proteins and the serum lipoids. Such changes are able to be brought about by a variety of substances which result in reactions clinically and therapeutically almost identical.

In such infections as the local staphylococcus infection of the skin and in some others in which, since Wright's first work, so many favorable reports have appeared it is quite possible that so far as immediate results are concerned a nonspecific foreign protein might act as well. However, in such cases there seems to be another factor concerned, namely, the specific immunity factor operating to prevent a recurrence of the infection. The nonspecific protein would probably not influence this factor and the use of autogenous organisms would be desirable for its immunizing effect. Therefore, where both a curative and preventive effect is desired, it would seem that the autogenous vaccine would be advantageous over a nonspecific protein substance, which might have only a curative action.

Subcutaneous injection of foreign proteins may behave quite like the intravenous injections, though the action is slower and the dose required for the desired effect is probably somewhat larger. On account of the very severe reactions occurring at times after the intravenous method, the question may be properly raised as to its possible dangers. Evidently further data are needed here, but if a proper reaction can be elicited by subcutaneous use, this route might be preferred on account of simplicity and perhaps safety. Even subcutaneous use of large doses may not be entirely free from harm. The writer knows of a case which, following a large subcutaneous dose of dead meningococci, developed a typical reaction manifested by a severe chill in thirty minutes, followed by fever of 103, nausea, vomiting, with leukocytes on the third day numbering 45,000. On the second day the urine contained albumin and large numbers of granular and hyaline casts, which persisted for several days.

An enormous number of patients are now being treated and will be treated throughout the country by this method. Much of it will be done by inexperienced men and no doubt we may expect some serious accidents to occur. I think it behooves us to take a conservative stand in the administration of these preparations and to advise strongly against the use of all sorts of unstandardized bacterial products which are now offered and will be offered to the profession.

In case it is shown conclusively that, for therapeutic purposes, any foreign protein may serve, the logical preparation for use would seem to be a sterile pure chemical preparation of some proteose, which can be carefully standardized. Such a substance would be far more reliable and satisfactory than the various vaccine mixtures and extracts now flooding the country.

SUMMARY

Recent work tends to show that many substances, the so-called foreign proteins and their derivatives, may, when injected especially into the veins, quickly cause a severe chill followed by high fever, leukocytosis and certain changes in the blood, especially the appearance of ferments. These proteins may be derived from disease germs or they may consist of other animal substances, as serum, proteoses and milk. After the rather severe reaction, marked improvement and even permanent cure may result in certain diseases, especially typhoid, and in rheumatic and gonococcus infections. This may be due to the high fever and to increase in the ferments and leukocytes of the blood. Other factors are probably at work.

The nonspecific effect of vaccines is just now probably the most important problem that concerns the vaccinationist. The possibilities of development along this line are many, for the principle concerns an immense number of diseases, both in man and the lower animals. Questions concerning ultimate cure, recurrences, relapses and dangers cannot now be justly appreciated because of lack of data.

This form of treatment should be referred to neither as specific nor as vaccine therapy. It is nonspecific, and usually, but not necessarily, protein therapy.

The important domain of vaccines is protective, not curative, according to present data.

CLINICAL EXPERIENCE WITH THE USE OF VACCINES IN DISEASES OF THE EAR, NOSE AND THROAT *

GEORGE MORRISON COATES, A B, M D
Fellow of the American College of Surgeons
PHILADELPHIA

In the consideration of such a subject as is indicated by the title, it is evident that full justice cannot be done to each disease of the upper air passages with which immunotherapy has been tried The option will therefore be exercised by the writer of selecting those which have been most extensively studied or are most prominently before our branch of the profession today, and endeavoring from the works of others, as well as from his own experience, to arrive at a just appreciation of their present value He may as well confess at the start that he is a believer in this form of treatment, although admitting that it is often far from satisfactory in the light of our present knowledge He feels somewhat diffident in presenting this subject to you and commenting favorably on the results obtained, in view of the present tendency to belittle vaccine therapy, either prophylactic or curative, specific or nonspecific

In reality, only the threshold has been passed in the study of immunology as applied to ear, nose and throat diseases, many problems remaining to be investigated, among which might be mentioned improved methods of taking cultures and of determining the infecting organism or organisms, the preparation of more efficient vaccines, whether by sensitization or otherwise, some accurate method of counting organisms and of determining the dosage for different organisms and different individuals And it is well to sound a note of warning at the outset, that vaccine therapy, much as may be hoped for it in the future, will probably never supersede the surgery that is necessary for drainage and for the correction of abnormalities that by their presence keep up irritation of the tissues and thus are conducive to reinfection by the same or another type of organism Much as we should like to immunize permanently against everything, in spite of such malformations, it seems hardly probable that this Utopia will ever be reached

In the popular craze for giving vaccine treatments which has pervaded alike the specialist and the general practitioner, vaccines have been administered for every known and unknown disease, with reason or without, more often the latter This has been, to a large extent, due to the many commercial brands on the market and the often absurd claims put forth for them by their makers By this it should not be inferred that these popularly called stock vaccines are without use or value, for many men have obtained results by their employment From the very nature of the case their use is imperative in certain conditions, even the much abused mixed varieties, often miscalled polyvalent, and these vaccines must not be confused with the stock suspensions of the home laboratory, also at times a most useful product Warning must also be issued against the confusion existing in many minds, or at least on many tongues, and this not by any means confined to the laity, between serology and vaccine therapy It is needless to define the terms to this audience, but bacterins are so often miscalled serums that it has seemed necessary to call attention to these two distinct immunity-producing methods of treatment, since only the first will be considered here

THE NOSE

Acute Rhinitis—Probably the most general adaptation of vaccines to ear, nose and throat practice has been their use for the prophylaxis of acute rhinitis or common cold, not only by the specialist, but by the general practitioner, the country over So much so, indeed, that patients now demand the so-called serum treatment The mere fact that it has come into such general use by physicians and general demand by the laity would indicate at least some value in this method Most of the immunization is, of course, necessarily done with the aid of commercial mixed vaccine of the many well-known different brands on the market It would be manifestly impossible to culture the causative organisms for the next cold from every nose at present in healthy condition, although it is probable that in a certain proportion of cases organisms would be obtained from which competent vaccines could be made In case the patient is subject to repeated acute colds, cultures taken during one of these may be used for vaccine preparation and prophylaxis against future ones, with most excellent results

Taking it for granted then that the use of vaccines for the prophylaxis of acute rhinitis is of value, one would naturally ask of how much value this method is Many cases, of course, will fail to respond, due probably to the fact that the organism causing the cold is not in the vaccine used whether it be autogenous or commercial mixed For it is quite possible that in taking the culture from the nose the causative organism may not be obtained In this relation the work of G B Foster,[1] recently published, in which he seems to demonstrate as an etiologic factor in acute rhinitis minute filterpassers or filterable toxins, would very readily explain these failures By accepting this work as being of great value, we must not forget that the old, well-known organisms do cause a certain percentage of rhinitides, or at least by secondary infection prolong them to their customary length, and when due to them, vaccine treatment will prevent or cure a very considerable proportion

The duration of immunity depends much, of course, on the amount of exposure, the individual peculiarities of the patient, the amount of vaccine given, and the presence of epidemics For instance, a patient subject to attacks of acute rhinitis every few weeks may be so immunized that the interval will be stretched to six, eight or ten weeks or longer The individual who has one or two bad colds during the winter may be immunized so that he will go from year's end to year's end without any These immunized patients frequently start apparently to have colds, that is, sneezing, sniffling, coryza, etc, which symptoms pass off in the course of a few minutes or a few hours This is readily explained if we consider the probable etiology of many colds Change in temperature of the air inspired or impinging on certain dermal surfaces excites reaction in the vasoconstrictor and vasodilator and secretory centers and a corresponding relaxation of the nasal mucosa, an increase of blood, secretion, sneezing, etc Here it probably is that the infection takes place and prolongs the cold If the patient is immune to infection the cold disappears with these few symptoms

* Read before the Section on Laryngology Otology and Rhinology at the Sixty Seventh Annual Session of the American Medical Association, Detroit, June 1916

[1] Foster, G B The Etiology of Common Colds The Journal A M A, April 15 1916 p 1180

In this connection, a word or two on the treatment of acute colds is appropriate If colds are treated early, there is no doubt that a great many of them may be stopped short, that is, within twenty-four hours But, of course, to do this an autogenous vaccine cannot be used, nor can a bacterial diagnosis, as a rule, be made on account of the shortness of the time Acute tonsillitis is in precisely the same category The well-known role that acute rhinitis in repeated attacks plays in diseases of the ear will at once convince the aural practitioner of the value of this prophylaxis While the actual condition may or may not be improved by the vaccine, there can be no question that the lengthened interval between attacks and the diminished severity of them makes it possible to obtain results in the treatment of recurrent acute catarrhal otitis media and chronic catarrhal otitis media that are not possible without some such method of treatment for the nasal condition

Accessory Sinuses—What has been said here in relation to diseases of the ear applies equally to acute and recurrent diseases of the accessory sinuses of the nose Vaccines, as a rule, have but little influence on suppurations of the various sinuses, except under certain conditions When free drainage is obtained the use of appropriate potent vaccines will usually hasten a cure Or if given before operation the individual's immunity will be so raised that it will accomplish the same result But, as in diseases of the ear, perhaps their greatest value is in preventing the recurrent acute infections that so often terminate in an attack of sinusitis The reports would indicate that the use of vaccines in cases in which the given sinuses are filled with pus with insufficient drainage is entirely useless

Much of what has just been said is, of course, well known and to a certain extent may be considered established, although the numerous failures that everybody has have produced many pessimists in regard to vaccine therapy

There are two new subjects to be included under the title of this paper that are of interest, besides the pollen treatment of hay-fever, which is not, of course, a vaccine treatment, although it approximates it and will, therefore, not be considered

Ozena—The treatment of ozena by any method has, as every one knows, been most unsatisfactory, and commissions have, at times been appointed by various national scientific societies to study the question, but without obtaining any results Within the last few years Hofer of Vienna, working in collaboration with Kofler, unearthed the forgotten contention of Perez that a bacillus, supposed to be of the Friedlander group and called by him the *Bacillus ozaenae-foetidae* was the cause of ozena, and could be found on and isolated from the mucosa underlying the crust Two of the early workers in this field were Skillern and Holmes[2] of this section and their report was one of the earliest Their findings were, as far as they went, similar to the above Hofer and Kofler followed the lines laid down by Perez, and later Skillern, treating their patients with vaccines, not autogenous, but made by themselves from half a dozen different strains, and therefore polyvalent Their results, while by no means uniformly good, were on the whole very encouraging, and a number of Americans in the last two years have studied with Hofer and have obtained various results by his own or modified methods Some reports have given us total failure, others, notably Horn of San Francisco and Klenk and Guggenheim of St Louis, claim almost universal success

Horn, however, disproves the contention of Hofer that the *Bacillus ozaenae-foetidae*, or the coccobacillus, as he calls it, is at all related to the Friedlander group, but claims that it is a motile and flagellated organism similar to, if not identical with, that which causes distemper in dogs, the *Bacillus bronchosepticus* He uses agglutination tests to aid in his diagnosis and administers to his patients a polyvalent stock vaccine of his own preparation and claims almost 100 per cent of improvements or cures Klenk and Guggenheim prepare autogenous vaccine for their patients with good results If Horn's contention proves to be correct, that the coccobacillus is not of the Friedlander type, but belongs to the colon and typhoid group, it would seem that most investigators have been on the wrong track and have been working with the Friedlander itself, which is probably a normal inhabitant of the nose In this connection, however, Friel[3] claims excellent results from the intravenous injection of a sensitized living vaccine of Friedlander's bacillus He gives this in very small doses, 2 million only, and avoids severe constitutional symptoms If the etiologic factor in ozena is not an organism of the Friedlander group, this treatment would only avail by immunizing against a secondary Friedlander infection, which might improve the patient's condition greatly Indeed, the writer has seen some apparently good results with a killed, nonsensitized vaccine of this organism given hypodermically

Dan McKenzie of London, a keen and usually capable observer, has just issued a claim and offered proof, that ozena is a manifestation of tubercular infection, not nasal, and believes the acid-fast bacilli which he invariably finds underlying the crusts to be attenuated forms of tubercle bacilli His reasoning in reaching this conclusion is out of place here, but he claims very great improvement, if not cure, following tuberculin treatment, the usual small dose, without reaction, being used While he noted marked improvement in a large percentage of cases, he found a tendency to relapse following the cessation of treatment There was also a concomitant gain in strength and health

Asthma—Babcock, as well as others, has called attention to the value of autogenous vaccines in the treatment of essential asthma, and it seems not out of place to refer to it in this paper He considers essential asthma to be an anaphylactic reaction to some form of foreign protein, whether it be animal emanations, pollen, food substances, such as fruits, vegetables, meats and shell fish, bacterial proteins from the accessory sinuses, the ears, the tonsils, pyorrheal pockets, gastro-intestinal absorption, gallbladder infection, etc His method of combating this distressing infection is to search most industriously for the source of the protein absorption and to eradicate it, if possible, using an autogenous vaccine, in addition to the surgery, if the focus is found in the body Besides that, or if no such focus is found, he makes an autogenous vaccine from the bronchial sputum, which can always be obtained in large quantities in these cases

He finds the usual organisms of bronchitis or tracheitis and in addition an anaerobic organism, which he cannot classify, but which he believes to be the main cause of the asthmatic attacks, and whose inclusion in the mixed vaccine prepared seems to be necessary. By this technic he claims that most patients with essential asthma, uncomplicated by organic disease of the heart or kidneys, can be cured or at least permanently relieved. This is of the utmost importance to us who make a study of the diseases of the upper respiratory tract, and must of necessity be intimately connected with our line of work. It emphasizes perhaps as much as anything else the fact that we must not depend on vaccine alone for the treatment of our patients. The necessary surgery to secure drainage and the eradication of foci of infection is absolutely essential, and given these conditions, and an intelligent use of vaccines, great results may be anticipated. And this applies not only to asthma, but to all diseases of the ear, nose and throat.

---

[2] Skillern R H, and Holmes E B New York Med Jour Aug 15 1908

[3] Friel Lancet London January, 1916

THE EAR

There are six more or less distinct conditions of aural infection, all but one related to each other, in which vaccines have been used with some degree of success, and it is proposed to consider them in their order of severity.

Otitis Externa Diffusa et Circumscripta (Furunculosis of the External Ear).—It is well known how trying, though seemingly how trivial, this affection often is to patient and physician alike, and its well-known tendency to a succession of infections or recurrences in one or both ears or alternating between the two. It is analogous to the ordinary acne vulgaris, but it is not identical with it, and it is preeminently a very localized process and distinctly amenable to vaccine treatment. As the furuncle yields ordinarily to local treatment or is self-limiting, it is not until there is a succession of them that there is a distinct call for more definite immunization and prophylaxis against the recurring crops. Then a vaccine made from the infection evacuated by the knife will often prove most efficient in terminating the trouble. For treating the initial lesion this is manifestly impossible since by the time pus has formed in sufficient quantity for obtaining a culture that particular infection is almost at an end.

If from the history of the case it is feared that there will be more following, the wise immunologist will proceed to have a vaccine made and administer it to guard against this contingency. In case the infection is of that obstinate, painful type that shows no tendency to localize and soften, to "point," in common parlance, a stock vaccine may be utilized, since most, if not all, of these infections are caused by either the *Staphylococcus albus* or *aureus*. Left-over suspensions of these organisms, prepared for the treatment of other patients and properly preserved, frequently answer well for this purpose, or for use pending the preparation of an autogenous vaccine. If these preparations were polyvalent perhaps they would be more uniformly successful even than they are, although frequently they are most efficient. Naturally, if the infection has localized and pus is present there is a positive indication for drainage, whether vaccines are used or not. If they are a very fair prognosis for freedom from recurrence may be given.

Acute Catarrhal and Suppurative Otitis Media.—Like the preceding, acute catarrhal otitis media is a more or less self-limited affection hardly calling for the artificial production of immunity except in the treatment of the nasal condition in which it has its origin. However, if we have it in the recurrent form, cultures taken from the tympanum, or in default of this, from the nasopharynx, will produce a vaccine that will have a distinct limiting and prophylactic effect. Here again necessary drainage must be obtained either through the eustachian tube or the membrana tympani, and the contributory tonsils and adenoid removed. It must also be remembered in estimating the results in this as well as the more severe variety of the same disease, acute suppuration, that the natural tendency is to get well, almost in spite of treatment, and the mere fact that this is accomplished must not be attributed solely to the vaccine until a large number of cases has been carefully studied in detail. This has been done by Weston and Kolmer, as quoted in a previous paper, and it was shown that in a large number of cases the length of time for cessation of discharge in these suppurations was very materially reduced by the preparation and administration of autogenous vaccines.

Chronic Catarrhal Otitis Media.—So far as the writer can learn by a search of the literature, by his own experience or by the process of reasoning, vaccine therapy can have but a small direct influence on our chronic catarrhal ears. In these the damage is done, and except for the treatment of the tubal and nasopharyngeal condition, aggravated by repeated acute nasal infection, which has been discussed above, little can be expected from it. In this latter respect, however, results, albeit not brilliant, may be obtained.

Chronic Suppurative Otitis Media.—Some years ago, when it was first announced that the use of vaccines would in large part supersede the accepted methods of treatment for chronic suppurative otitis media, much doubt was expressed, and many workers took up the question to achieve, in the main, only disappointment. While not as brilliant, on the whole, as many were led to expect from one or two notable series reported, the method undoubtedly has its uses, if also its limitations, and it is the feeling of the writer that it should always be given a fair trial before proceeding to the court of last resort, namely, the radical operation, except where very distinct contraindications exist that may endanger life by delay or at least make all chance of success hopeless. Such contraindications are any symptoms pointing to the imminence of intracranial involvement, probably labyrinth suppuration, extensive caries of the tympanic walls, chronic mastoiditis and cholesteatoma.

However, even when success is not obtained by the use of vaccines in this condition and it eventually becomes necessary to proceed to the radical operation, the ground has been well prepared, a certain amount of immunity established, and the chances are that healing will be more rapid and satisfactory. The treatment of chronic suppurative otitis media by vaccines is perhaps as complicated and difficult as that of any other disease in the body. Almost always a mixed infection, it is extremely difficult to detect and isolate the causative organism or organisms, and all depends on the technic employed and the success obtained in this very first particular. The method adopted by most workers in this line is to cleanse the external canal and middle ear thoroughly by swabbing or suction, sterilize with alcohol for various lengths of time, then by inflation or suction, produce a drop of pus or moisture in the middle ear and from this take the culture with a sterile platinum loop. In this way only can contaminating saprophytes be avoided. The sterilization may be too complete, in which case no growth will result and it will be necessary to repeat the process, but no particular harm has been done other than the delay of a few days

With a potent vaccine made from the proper organism results will depend on the proper dosage, intervals between doses and possibly to a certain extent on the local treatment which should be carried on simultaneously with the vaccine administration, except when cases are being cared for by this method experimentally to determine its value In these cases, no local treatment should be given If a case is about to respond favorably to the vaccine, a local reaction is first obtained on the arm at the site of injection and a focal reaction in the ear consisting usually of a sensation of heat, an increase and a thinning of the discharge, followed after a few days by a diminution and thickening If no improvement is observed after five or six doses have been given, or if improvement has followed up to a certain point and then ceased, the vaccine treatment is discontinued, the patient allowed to rest for a few weeks, and further cultural studies made of the ear, at which time it may be determined that the type of organism has changed and that a fresh vaccine will be made up of a new group of organisms No one is justified when a mixed culture is obtained, as it usually is, in picking out one or two organisms and discarding the others All organisms included when the culture has been taken in the way outlined above should be made into vaccine By this it is meant they should be plated out and grown separately and mixed finally Many early failures in the hands of the writer were due to arbitrarily picking out certain organisms which were thought to be causative and discarding others, notably the *Bacillus pyocyaneus,* which was not supposed to be pathogenic It was found, on the contrary, that the *B pyocyaneus* when included in the mixtures or when used in pure cultures, gave probably the best results of all vaccine treatment

It is impossible to say in what proportion of chronic suppurative otitis media the discharge can be arrested It is not well to use the word cure because of the well-known tendency to recurrence after any method of treatment, and while it seems probable that this tendency is much less after proper immunization, still it must be recognized that it exists In studying results also, just as in the acute diseases mentioned above, it must not be forgotten that many of these ears become dry under ordinary treatment or even without, so that due allowance for this must be made In arriving at conclusions as to the value of vaccine in this disease, care should be used in excluding as far as possible this spontaneous result by taking only cases of proved chronicity which have been under all other methods of treatment for a long period of time

A series of fifty cases of this type, recently reported by the writer and his assistant, M S Ersner, showed dry ears obtained in only 46 per cent But in view of the fact that otherwise all of these cases would have gone to radical operation for a cure, it would seem that something has been gained The problem here, it would seem, is to find some method of determining which organisms are the true pathogenic ones This was attempted last year in connection with the series just mentioned and twenty-five complement fixations were done on these cases, with a negative result in all The reasons for failure were possibly the facts that only three polyvalent collections of organisms were used as antigens or because of the extreme local character of the process in the middle ear and the constant lack of sufficient antibodies in the blood to give the reaction Much work might be done along this line to very great profit In this same series of cases there were no positive Wassermann reactions among the failures, but there were five positive von Pirquet tests

Mastoiditis and Its Complications—No one will advocate dependence on vaccines for the treatment of a case of acute mastoiditis if this is avoidable, though it is conceivable that they may be used if for some reason operation is out of the question or might bring added danger There would be no objection to their use during the period before operation of a slowly developing mastoiditis They would at least do no harm and would probably raise the patient's resisting power sufficiently to make quick recovery possible They must, however, in no sense be considered to take the place of the mastoid operation in case this is possible and imperative, but several times in the practice of the writer, and many times by personal reports to him from other practitioners, the administration of vaccines has put a definite check to a slowly progressive mastoiditis or has been the determining factor toward resolution in one that was at a standstill

While definite failures to produce this result have also been reported, it is the opinion of many that it is often a useful procedure That it is dangerous teaching is evident, as it may hold out hope for recovery until the time of election for operation is past, and vaccine should therefore be used with the greatest care and judgment in mastoiditis and the indications for operation closely watched At the time of operation, pus recovered from the mastoid should always be sent to the laboratory for bacterial diagnosis, and it is the writer's custom either to have a vaccine made at once or at least to keep subcultures going until it is determined that a vaccine will not be needed The first method is preferable, as it is very little more troublesome and the vaccine is ready for use if the case does not progress satisfactorily Indeed, it would seem wise to use the vaccines in all cases as soon as prepared after operation, since healing is more prompt by their use When we come to intracranial complications and general septicemia, vaccines are of no avail In this acute general process antitoxins and serums should be the more scientifically correct, but evidently do not seem to have been of very much use in practice

STOCK VACCINES

The writer has an open mind as to the relative values of autogenous and stock vaccine That the latter is often of value in cases in which the autogenous product has failed is beyond question from any one who has done much of this work Indeed, the whole theory of prophylactic immunization depends on this fact, so well exemplified in the case of typhoid fever So far as it has gone, also, the vaccine treatment of ozena by a polyvalent stock vaccine has proved eminently satisfactory in the hands of Horn It can readily be seen how this may be so, if the suggestion of a basic protein common to all bacteria, or at least to associated groups, be accepted, giving at least partial immunity, and it is equally evident that it may fail in certain instances, notably the streptococcus group, since there are so many different varieties with widely separated characteristics and of greatly differing degrees of toxicity

The subject of bacterial therapy is an absorbing one to most practitioners, and since commercial vaccines have been supplied in such quantities and made so readily obtainable, it has been used by thousands who doubtless understand little of the therapeutic action of the agent being used Frequent warnings have been issued against the indiscriminate use of vaccines and the dangers attendant on their employment The question is often asked whether under the circumstances a nonbacteriologist is justified in their use and if the danger is not greater than the chance of cure The writer, while he formerly inclined toward this view, after having given several thousand injections in clinic and in private practice and being cognizant of as many more, has yet to see any more harm result from their use, even if not always intelligent, than from an equal number of ordinary hypodermic injections One or two cases have been reported to him with somewhat severe reactions, alarming at the time, but this may happen with almost any form of therapy Of course the claims of the makers of commercial vaccines are usually absurd and misleading, although it is surprising how many men of intelligence will accept them at times, even in the face of all reason

SUMMARY

To summarize briefly, the writer feels that if vaccines have not fulfilled all of their early promise, they have at least given us a very effective extra means of combating infection, especially if used in conjunction with skilful and intelligent surgery, and that little harm will or can result from their use, even by the novice, provided the injections are given hypodermically, rather than intravenously, as in the latter method the reactions are at times exceedingly severe and alarming In a number of instances, notably ozena, it seems as if vaccine therapy alone might solve a problem which has been puzzling clinicians hopelessly for years, and until some more efficient substitute is discovered, vaccine therapy has its distinct place as a therapeutic measure in diseases of the ear, nose and throat

1736 Pine Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS DAVIS AND COATES

Dr Daniel W Layman, Indianapolis I have had some experience in the use of autogenous vaccines in the treatment of cases of chronic suppuration of the accessory sinuses As far back as 1912-1913 I used the autogenous vaccine in the first group along with the regular routine treatment In almost all of these cases we established thorough drainage by operative procedure, whether it was a conservative or radical case, and after the effects of the operation subsided we commenced this series of cases with autogenous vaccines, made both in the regular way and by animal experimentation Most of these cases were of the staphylococcus type, *Staphylococcus aureus* predominating In the second group we used the autogenous vaccine without the necessary operative procedure These patients refused nasal surgery and so I carried them along as well as I could with only the vaccine Then in the third group of cases, just for comparison, I used the regular method of treatment without any vaccine whatsoever I think that my results were about the same as Dr Coates reports, that is, that the vaccine is a material aid in the treatment of chronic suppurative disease of the accessory sinuses along with the routine treatment and necessary nasal surgery In other words, it is absolutely necessary to establish thorough drainage and ventilation, and vaccine therapy per se, that is, without the assistance of other treatment, failed to be of any benefit as a therapeutic agent

In the third group I used routine treatment and operative procedures when necessary, but without the aid of vaccines Compared with the first group they did not do as well In other words, I found that autogenous vaccine is a valuable aid in the treatment of chronic suppurative conditions of the sinuses where the treatment has been given to establish proper drainage and aeration of the sinuses In regard to the treatment of acute rhinitis, I have not had any experience with autogenous vaccines, but I have had some experience with the stock vaccines Two or three men who worked in a drug house came to me with bad colds in the head They brought with them some stock vaccines and wanted me to try them out I did so and got fairly good results I did not use the stock vaccines during the acute attack, but waited until the acute attack was over and then gave the vaccine at three or four day intervals, about three or four doses altogether, increasing the strength from time to time The treatment with stock vaccines of ordinary colds not only with the clerks as above mentioned, but with other patients has been quite satisfactory

Dr John A Pratt, Aurora, Ill I have been lucky in my vaccine cases I have had very good results I use both the autogenous and the stock vaccines In cases in which I do not have the time to make the autogenous vaccine, I have taken the autogenous vaccine of other cases and mixed it with the stock vaccine and injected that In that way I thought I should be able to obtain a vaccine of the local germ, of a local infection that was going round, and these patients have seemed to improve Patients with sinus trouble have improved rapidly in my hands with vaccines It does not seem to make much difference whether it is autogenous or stock One case of tuberculous middle ear discharge ran a long time The patient, a woman, did not improve under the autogenous vaccine and at that time an old gentleman came in who had a running ear for years, so I decided to try this woman's autogenous vaccine on the old man I gave him three injections and the ear dried up and was cured That was about five years ago He was in my office before I came away and I asked him about his ear and looked at it and it was perfectly dry In the woman I had no improvement whatever This possibly may be, as Dr Davis indicates, leukocytosis but I have seemingly had some results from the vaccines

Dr David John Davis, Chicago Many phases of this problem are unsatisfactory to discuss at the present time We need more data and especially do we need control observations It is remarkable how few control data exist in vaccine work There is no doubt that reactions occur after vaccines and that good results have followed their use in some cases but the question centers around the idea of specificity In other words, have these reactions a specific curative value? At present, data are rapidly accumulating indicating the non specific character of the results It is an interesting fact that so far as animal diseases are concerned we do not know of any instance in which vaccines are curative This is in striking contrast to the role that vaccines play in animal diseases for prophylactic purposes This is true of natural and experimental animal diseases For example, Dr J J Moore has shown that in rabbits already infected with streptococci, vaccines have no appreciable effect on the course of the infection However, if the vaccines have been given some time previous to the inoculation the animal may be protected to some degree at least

Dr George M Coates, Philadelphia Laboratory men and clinicians are very apt to differ, and it seems to me very necessary that they should get together more closely than they have in the past Animal experiments prove a great deal from their standpoint, but it is only by using the results of these in combination with the work of the clinicians that we get ideas about the value of our methods of treatment In regard to specificity, I always supposed that if we did not get results with the autogenous vaccines it was due to the fact that we did not have the specific organism If this new theory is to be accepted it wipes that out—the stock vaccines will probably give as good results as the specific vaccines We are at the beginning of this method of therapy, after all

An Estimate—But nothing is more estimable than a physician who, having studied nature from his youth knows the properties of the human body, the diseases which assail it, the remedies which will benefit it, exercises his art with caution and pays equal attention to the rich and the poor—Voltaire

STUDIES OF THE GASTRIC RESIDUUM

I A STUDY OF EIGHTY SAMPLES OF GASTRIC RESIDUUMS OBTAINED FROM APPARENTLY NORMAL WOMEN *

CHESTER C FOWLER, PH D
AND
ZELMA ZENTMIRE, M S
AMES, IOWA

Extensive studies of the gastric residuum of normal men have been made by Hawk and collaborators[1] These investigations have demonstrated that the average volume is quite large (in over 100 normal cases the average was 52 14 c c), quite contrary to the views of Loeper,[2] Zweig,[3] Kemp,[4] Wolff,[5] Strauss,[6] Riegel,[6] and Soupalt,[6] who assert that the quantity of residuum in the normal fasting stomach should not exceed 20 c c Rosin and Schreiber[6] suggest a maximum limit of 60 c c for the volume of the gastric residuum A variation of from 17 to 180 c c in the volumes of the various residuums examined by Hawk further demonstrates the unimportance of the quantity of residuum as an aid in diagnosis These findings of Hawk and collaborators have recently been confirmed by Talbot[7]

The residuum is a physiologically active secretion[8] and is probably in part the result of the activity of the gastric glands[8] and in part the result of fluid which passes by osmosis[8] through the stomach walls into the lumen of the stomach The fact that bile and trypsin are both quite frequently found in the residuum leads one to believe that a portion of it at least is due to regurgitation of fluid from the duodenum[9] Swallowed saliva and esophageal secretions may also give rise to another portion[10] The last factor was greatly eliminated in the work of Hawk and collaborators[1] by encouraging the subjects to reject as much saliva as possible by expectoration That the residuum is not wholly due to saliva was clearly demonstrated by Fowler, Rehfuss and Hawk, in the case of Subject B 106 a This subject, normal in every way, submitted to the passage of the tube on the empty stomach in the morning Forty-nine c c of liquid were removed, and tests showed that the stomach was empty Two hours later, during which time the person in question attended a lecture, was free from psychic stimuli, and swallowed no saliva, 29 c c were withdrawn (Case B 106 b) Furthermore, these two secretions were essentially the same in every particular Carlson[11] has also demonstrated that a fluid is being continuously secreted into the empty stomach

The total and free acidities are subject to almost as wide variations as is the volume The total acidity, in the cases presented by Hawk, ranged from a minimum of 2 4 c c of tenth-normal sodium hydroxid to titrate 100 c c of juice (about 0 009 per cent acidity in terms of hydrochloric acid) to a maximum of 77 6 c c (about 0 28 per cent hydrochloric acid), with a mean average of 29 9 c c (about 0 11 per cent hydrochloric acid) The free acidity averaged 18 5 c c (about 0 07 per cent hydrochloric acid), with a range from 0 c c (0 per cent hydrochloric acid) to 65 8 c c (about 0 24 per cent hydrochloric acid) These acidities are much smaller than those given by Carlson,[12] and obtained from a subject with a gastric fistula The acidities of the contents of the empty stomach of this subject were 0 23 per cent hydrochloric acid and 0 18 per cent hydrochloric acid for total and free, respectively

A definite relation between the pepsin content of the gastric residuum and total acidity has been demonstrated for low acid values, but this relation has been shown to disappear as high acid values are approached (Fowler, Rehfuss and Hawk)[1]

The same investigators found trypsin to be present in practically every specimen of residuum which was examined for it Dorner[13] showed the presence of trypsin in practically all of the residuums obtained from 154 patients, most of whom had gastro-intestinal disturbances The cases reported by Hawk and co-workers[1] were nonpathologic The occurrence of trypsin in the stomach has been more completely studied by Spencer, Meyer, Rehfuss and Hawk[9]

The present investigation was undertaken for the purpose of determining whether or not there existed any pronounced differences between the residuums of normal men, and the residuums of normal women

METHODS

The subjects of the experiments described in this paper were young women students in the courses in physiologic chemistry at Iowa State College They willingly submitted themselves for the experimental work, and were requested to drink no water at any time after their evening meal on the night previous to the experiment They came for the removal of the residuum at 8 o'clock the following morning, and every residuum was removed as near that time as was compatible with the experiment Each woman was given a thorough examination, physically and by questioning, to detect any abnormalities if they existed

The residuums were removed by means of a modified stomach tube described by Rehfuss[14] The swallowing of the tube was accomplished without the aid of water The tube and tip were first coated with a thin film of petrolatum, and then the tip was placed in the lower part of the pharynx, back of the tongue, and swallowed without much difficulty When the tube had reached the stomach (which was ascertained by measurements), the contents were aspirated from it while the subject was reclining on her back, stomach and on each side and breathing deeply The liquid was immediately measured, placed in an Erlenmeyer flask, and its characteristics noted The residuum

was then filtered through moistened qualitative filter papers, and the first few drops of filtrate were discarded The following determinations were then made, as far as possible, on the filtered residuum total acidity, free acidity, pepsin and trypsin

The methods[15] for total acid, free acid and pepsin were those used by Rehfuss, Bergeim and Hawk[16] Trypsin was determined by the method of Spencer[17]

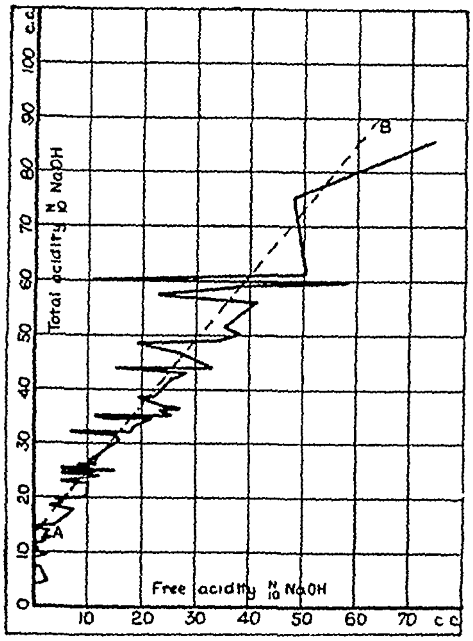

Chart 1 —Relation of total to free acidity of residuums

DATA

Eighty-one samples of residuums were collected from sixty different subjects, twenty-one of the subjects submitted to the passage of the tube twice

Averages on the Compilation of the Normal Gastric Residuum —1 The average quantity removed in eighty-one cases was 49 44 c c, the largest quantity being 135 c c and the smallest 12 c c

2 In sixty-nine cases noted, the residuum was in twenty-two cases (32 per cent) colorless, and in forty-seven cases (68 1 per cent) yellow or green

3 The total acidity recorded in eighty-one instances averaged 30 3 in terms of tenth-normal sodium hydroxid, with the highest figure at 86 0 and the lowest at 4 0

4 The free acid (seventy-nine cases) averaged 15 6, with figures ranging from 74 5 to 0

5 The pepsin concentration as measured by the Mette method was determined in seventy-nine cases, and gave an average[18] of $(3\,3)^2$, highest $(6\,7)^2$ and lowest $(0\,0)^2$

6 Trypsin was tested for in sixty-three cases, with an average of 5 2 units, ten cases gave 16 units, and fifteen no reaction Thus in 23 8 per cent of the cases there was no evidence of trypsin

7 Microscopic examination revealed on no occasion gross food residues On several occasions vegetable debris was found, but never meat fibers Leukocytes, in considerable number, were found almost constantly, and occasionally swallowed material from the throat with bacteria

COMMENT

In eighty-one cases the average volume of the gastric residuum of normal women was 49 44 c c This quantity is greatly in excess of the generally accepted limit of 20 c c, and very close to the average value of 52 14 c c obtained from over 100 cases of normal men[8] The range of volumes was likewise extremely wide (from 12 to 135 c c), similar to the range of from 23 to 160 c c obtained by Fowler, Rehfuss and Hawk[1] Hence in regard to volume there appears to be little or no variation in the residuums of normal men and normal women The volumes of the residuums obtained from women were *only* slightly lower than those obtained from men

Decided variations in the color of the residuums of normal women were observed (similar to variations observed in the case of men),[8] 31 9 per cent of the observed cases were colorless, while 68 1 per cent were colored This shows a slightly lower percentage of colorless samples and a slightly higher percentage of colored samples in the case of women than in the case of men (men 43 per cent colorless, 56 per cent colored)[8] Both colorless and bile colored residuums were obtained from the same individual at different times, and even were occasionally obtained during the course of a single aspiration This was especially noticeable after the subject had rolled from one side to the other The color is apparently controlled by the flow of bile through the pylorus into the stomach, rather than as Sartory[19] has suggested by the growth of a chromogenic yeast (*Cryptococcus salmoneus*) This point is being made the subject of an extended experiment in this laboratory and will be reported on in a later paper[20]

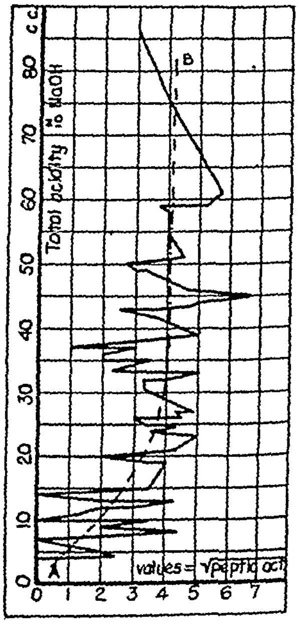

Chart 2 —Relation of pepsin content to total acidity of the residuums

The color is more often seen in cases of high acidity Of the forty-seven colored cases reported, about 85 per cent appear in acidities over 30, while only 15 per cent appear in acidities of less than 30 This would appear further to support Boldyreff's[9] idea of duodenal regurgitation to regulate gastric acidity

The relation of total acidity to free acidity is shown by Chart 1 As in the instance of the previously cited cases of men, free acidity is rarely encountered until the total acidity exceeds 10 In total acidities of over 14 there were no cases in which free acidity was not demonstrable (over 13 5 found by Fowler, Rehfuss and Hawk[1] for men) The greater number of the residuums lie between total acidities of 20 and 60

[20] Fowler Levine and More Unpublished data

(from 25 to 52 for men).[8] A few lie above 60, and considerably more below 20. The average total acidity was 30.3, and the average free acidity was 15.6 (the average acidities in the case of men were total, 29.9, free, 18.5).[8] The range in total acidity for women was found to lie somewhat higher (from 86.0 to 4.0) than it was found to lie for men (from 77.6 to 2.4),[8] and the same was true for free acidity, women, (from 74.5 to 0), men, (from 65.8 to 0).[8] Only two cases were above 70 in total acidity.

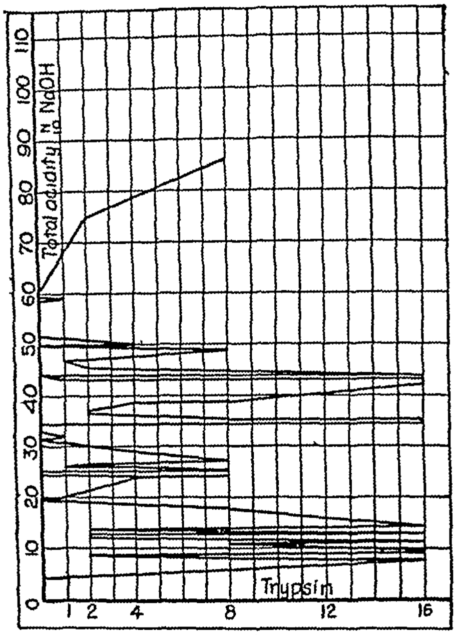

Chart 3.—Relation of trypsin to total acidity of residuums

In regard to acidities, and also volumes, it is worth mentioning that we have noticed at various times during our investigation a remarkable constancy in the volume and total acidity of residuums from the same person collected at widely different times. This point is worth further investigation.

Pepsin was tested for in every case studied but two, and was found in all cases tested, except three of low acidity. The average value[18] of peptic activity was $(3.3)^2$, somewhat higher than the value of $(2.8)^2$ obtained for men.[8] The highest value was $(6.7)^2$, compared to $(5.0)^2$ for men,[8] and the lowest were $(0.0)^2$, men[8] $(0.7)^2$.

In the case of women the same relationship between the quantity of pepsin and total acidity for low acid values is seen (Chart 2) as was observed in the case of men.[8] This view is contrary to that of Pawlow,[21] who asserts that no such relation exists. This relationship is likewise seen to disappear as high acid values are reached, more or less supporting the view of Gregersen[22] who states that the relation of pepsin to hydrochloric acid is not an absolute one. In none of our cases were we able to demonstrate the presence of pepsin in the absence of total acidity. Aliprandi[23] asserts that pepsin may occur in the absence of hydrochloric acid, and also that there is no strict parallelism between pepsin and hydrochloric acid.

The trypsin content of the gastric residuum of women was determined in sixty-three cases. Our results do not bear the striking similarity to the trypsin content of the gastric residuum of men[8] (only twenty-six cases determined) that the volumes, total acidities, free acidities and pepsins do. Charts 3 and 4 show the relation of trypsin to total and free acidity, respectively. From these charts the relation of trypsin to free acidity is not as evident as it was in the work on men.[8] Furthermore, several cases of low acidity were obtained in which there was no trypsin or only a little, while one case, the acidity of which was over 70, presented a trypsin content of 8. In the case of men,[8] a content of trypsin equivalent to 16 was not found above a free acidity of 20, several were found between 20 and 30 in the case of women. Of the sixty-three cases examined, fifteen, or 23.8 per cent., contained no trypsin as compared to 7.7 per cent. in the case of men.[8] An average value of 5.2 units was obtained for trypsin in the cases of women, as compared to 9.1 units for men.[8] This and the previously mentioned differences may constitute a fundamental difference between the residuums of men and women, but we are inclined, for the present at least, to consider these differences to be due mainly to the smaller numbers of cases examined in the work of Fowler, Rehfuss and Hawk.[1] This can be settled only by a more extensive investigation.

SUMMARY

1. No striking differences between the gastric residuums of normal women and of normal men have become evident during the course of this investigation.
2. The accepted limit of 20 c.c. for the volume of the residuum of the empty stomach of normal women is too low. An average volume of 49.44 c.c. was obtained in eighty-one cases.
3. Both colorless and bile-colored residuums may be found. The two may occur in the same individual on different days or during the same aspiration.
4. The colored residuums are found more frequently in higher acidities. This is explained, as before, by the greater frequency of regurgitation in higher acidities.

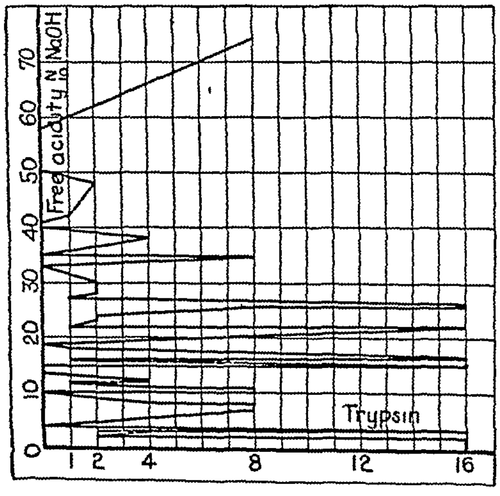

Chart 4.—Relation of trypsin to free acidity of residuums.

5. Total and free acidity vary directly with each other, free acidity rarely being found with a total acidity of less than 10, and always being found when the total acidity was greater than 14.
6. Two cases were observed in which the total acidity was greater than 70. In general, the total and free acidities of the residuums of the women subjects

observed run higher than those of the men subjects reported by Fowler, Rehfuss and Hawk.[1]

7. The definite relation of pepsin to acid in low acid concentrations has been confirmed. Also, this relation is seen to disappear as high acid values are approached.

8. The trypsin content of the gastric residuums obtained from women was shown not to bear the striking inverse relation to the free acidity that was demonstrated to be true in the case of residuums obtained from men.[5] This is thought to be due to the larger number of samples examined in the present investigation, and not to be due to any fundamental difference in the residuums of men and of women.

ABSOLUTE DIABETES WITH RETURN OF FUNCTION

REPORT OF A CASE *

C. D. CHRISTIE, M.D.
CLEVELAND

By an absolute diabetes is meant one in which the patient so afflicted is not able to utilize any carbohydrate which is taken in the food or any of the sugar which is yielded from protein metabolism. There is no very good evidence that fat is converted to sugar in the diabetic. All diabetics of the severity of this case, it is reasonable to assume, have no deposits of glycogen in their tissues. The only two sources for sugar, then, would be that which was fed to the patient and that derived from the breaking down of the protein molecule. Each 6.25 gm. of protein which is utilized in the body is represented by 1 gm. of nitrogen excretion. Practically all nitrogen is eliminated through the kidneys. Since fats are not converted to sugar, and since there are no glycogen deposits in the tissues, it is readily apparent that any sugar which is excreted in the urine of a starving diabetic must come from the protein. If the total nitrogen output and the total sugar output are determined for twenty-four hours and the former divided into the latter, it will give the ratio of dextrose to nitrogen excretion or the amount of sugar which is derived from the utilization of 6.25 gm. of protein. We know experimentally that each 6.25 gm. of protein taken into the body will yield 3.65 gm. of sugar; therefore a patient who is excreting 3.65 gm. of sugar for each gram of nitrogen in the urine is an absolute diabetic, or cannot utilize the sugar which is derived from the body protein.

A dextrose to nitrogen ratio of 3.65 : 1 occurring in diabetics was termed the "fatal ratio" by Lusk.[1] Certainly a better terminology could not have been given the condition. Practically all of the patients who have been reported who have shown this "fatal ratio," have died. Greenwald,[2] Foster,[3] Geyelin and Du Bois[4] have reported cases in which there has been subsequent return of sugar tolerance. In none of the three cases just cited was starvation employed during the entire course of the high dextrose to nitrogen excretion. In the case I am describing, starvation was practically continuously adhered to from the time it was started, until the patient became sugar free. I feel confident starvation was the factor which shortened the course of the "fatal ratio" period in this case, and without its aid our patient would doubtless have succumbed to his severe diabetes combined with the infection which he had with acidosis. After a brief critical period of four days, the patient was free from all severe diabetic symptoms. The starvation was not a hardship for him. Besides, from fear of the danger of starvation, he never complained after the second day of the prolonged fasting.

REPORT OF CASE

History.—D. M., man, aged 26, white, carpenter, was first admitted to Lakeside Hospital, April 8, 1915, and was discharged three weeks later. His complaint at that time was extreme weakness and dull aching pain across the lower portion of his back. There was no history of any other member of his family having been afflicted with diabetes. The past history was negative aside from measles when a child. The present trouble dates back to April, 1913. While engaged in some light work the patient suddenly became very weak and was unable to continue. He immediately went to see a doctor who told him he had sugar in the urine. He remained away from his work for a short time and was cautious with the food he ate; he immediately felt much improved and resumed his regular duties. For six months he remained comfortable. He then commenced to have excessive thirst, increased urine output, persisting weakness and gradual loss in weight. Since that time his condition had been variable; some days he felt good and other days he was totally incapacitated, depending on how closely he adhered to his diet. During the last three months, the patient had been having numerous boils and pains in his back and legs.

Physical Examination.—The patient impresses one as not possessing average mentality; he talks at random and asks countless questions during the day. He is a well developed man but extremely poorly nourished. His weight prior to the onset of this trouble was 156 pounds; he now weighs 125 pounds. He is extremely weak and prefers to lie on the bed. His actions and movements are those of a senile man. There is a very marked sweetish odor to the patient. Skin and mucous membranes are dry and parched. There is a bright scarlet hue to the skin about the face and neck; he looks as if he were sunburned, but has not been exposed to the sun. Nothing abnormal was observed from an examination of the eyes and eye grounds or the nose and ears. The teeth are in moderately good condition, but there is a marked pyorrhea alveolaris. The tonsils are small and show no signs of infection. Heart, lungs and abdomen are normal. Reflexes are slow and sluggish in response, but there are no other abnormal findings from the neurologic examination.

The Wassermann reaction is negative on blood and spinal fluid.

Urine examination shows 97 gm. of sugar in the twenty-four hours. The acetone and diacetic reactions are very distinct.

During the patient's stay of three weeks in the hospital it was not possible to get his sugar output below 45 gm. in the twenty-four hours by strict dieting. He was feeling much better, however, and insisted on going home, so he was discharged.

During the time from his first admission to the last one with which we are interested, nothing more was heard of the patient until he presented himself to our dispensary, Jan. 14, 1916. He was promptly admitted to the hospital.

Record of Last Admission.—D. M. was admitted to the medical service for the second time Jan. 14, 1916. His complaint at this time was a severe cold and a boil on the back of his neck, both of which developed about one week before. Since his discharge from the hospital April 21, 1915, his condition had been variable, a part of the time he was able to work. He volunteered the information that his diabetes was better and his only trouble was the cold and boil.

[4] Geyelin, H. R., and Du Bois, F.: A Case of Diabetes of Maximum Severity with Marked Improvement, THE JOURNAL A. M. A., May 13, 1916, p. 1532.

The most striking things about the patient which had not been so noticeable at the previous examination were a greater degree of emaciation, and an appearance of being extremely sick In addition to the findings of the former examination there was a carbuncle about 4 cm in diameter on the left side of the patient's neck It had the usual multiple openings, and there was a slight amount of purulent discharge It was extremely red and swollen, with pronounced induration, there was only a moderate amount of pain in connection with it The patient had a slight elevation in the pitch of the percussion note, with higher pitched breath sounds over the upper right posterior portion of the lung No rales Aside from these noted facts there was nothing made out in addition to that described in the previous physical examination

Jan 15, 1916, the patient was started on a test diet in the morning This diet consisted of 16 gm of nitrogen and 50 gm of carbohydrate Twenty-four hour urine started at 7 a m There was a distinct "acetone odor" to the patient's breath His respiratory rate was 25 to the minute but he was wide awake and did not appear to be in any immediate danger of coma

January 16, the patient was still on the test diet, and was eating every particle of food served him There was a daily elevation of temperature to 101 F His condition was apparently worse than the day before, but there was nothing evident to explain why it should be

January 17 the patient was started on starvation He was being given 180 c c of whisky daily, black coffee as desired, and 30 grams of sodium bicarbonate every four hours by mouth The general condition was much the same as the day before

January 18 starvation was continued The patient was considerably worse The tension of carbon dioxid in the alveolar air had dropped to an alarming figure The respiratory rate was averaging around 25 He was more drowsy than he had previously been, and he was taking very little interest in things about him We considered the advisability of terminating the fast and giving sodium bicarbonate intravenously

January 19, starvation was continued The patient seemed better, there was a slight increase of the carbon dioxid tension

January 20 on account of the demands of his friends he was given a small amount of food He was much better he seemed much wider awake and said he felt better The whole carbuncle area had sloughed out, leaving the muscles of the neck exposed The area now measured about 6 cm in diameter Nothing was being done for it except hot dressings at frequent intervals and keeping the area clean

January 21 the same amount of food was given the patient as the day before He was much better, but the sugar in the urine had apparently struck a constant level and would not diminish The small amount of carbohydrate had apparently lowered the dextrose to nitrogen ration However, it is a question in my own mind whether the 10 gm of carbohydrate which the patient received was absorbed in his blood stream as dextrose It was given in the form of greens, and they appeared in the stool unchanged Had they not been utilized the dextrose to nitrogen ratio would have been 2 6 1 on these two days instead of the figure given in the table

January 22 the patient was again started on starvation He was improving rapidly so far as his general appearance was concerned The tension of carbon dioxid was gradually coming up

January 24 starvation was continued, as it had been the day before General condition was much better The patient complained very little because food was not given him

January 25 starvation was continued It will be noted that there was a sudden drop in the protein metabolism the day before as indicated by the nitrogen output Although the dextrose to nitrogen ratio continued nearly the same the diminution of protein metabolism was looked on as a good omen

January 26 the patient was much improved The sugar output and dextrose to nitrogen ratio had dropped very decidedly Starvation was continued There was a sudden rise in the dextrose to nitrogen ratio of the preceding day This perhaps was due to the fact that the patient ate a small amount of oatmeal which he took from another patient's tray It was dry oatmeal without cream or sugar, and attendants on the ward thought he obtained a very small amount

January 27 starvation was continued The sugar output and dextrose to nitrogen ratio had both come down very decidedly

January 28 the patient had but a trace of sugar in the urine in the morning and it was decided to start food immediately He was given 10 gm of carbohydrate in the form of 5 per cent vegetables and 25 gm of fat This amount was divided into six feedings for the day The patient was decidedly improved The alveolar carbon dioxid tension was back to approximately a normal figure The area on the patient's neck was much improved granulation tissue was beginning to form with great rapidity, and there was very little discharge

January 29, the patient's urine became sugar free His food was increased to 20 gm of carbohydrate and 50 gm of fat

February 1 the urine remained sugar free, the patient was taking 30 gm of carbohydrate Total food intake was 1,440 calories, of that amount about 500 calories were derived from whisky

February 8 the urine remained sugar free The patient was taking about 1 950 calories daily

February 16 the patient's condition continued to improve There had been only a trace of sugar in the urine on two occasions There was an acetone reaction still persisting in the urine The patient was now taking 45 gm of carbohydrate daily, or a total intake of 2 390 calories There was some slight discharge from the neck, but granulations had largely closed in the area

February 25 there was sugar in the urine on two successive days his tolerance was exceeded He was given a starvation day which promptly eliminated the sugar from the urine He was now taking 2 500 calories daily

February 28 he had remained sugar free since the instance just recorded He had been having a daily rise of fever since the day of admission It had varied usually never exceeding 101 F Today was the first day he was free of fever The physical signs had not varied in the lungs We were fearful of a tuberculosis and that the prolonged starvation and undernourishment might revive it If that were the case, however, we were not able to demonstrate any alteration in the lung condition

March 5 1916 The patient had been free of fever since February 27 There had been a trace of sugar in the urine on a couple of days since February 25 The area on the neck was covered by a small scab there was no discharge The physical signs in the chest were just the same as they were on admission He was now taking carbohydrate, 60 gm, protein, 55 gm and fat 225 gm or a total intake of 2 500 calories The patient was quite comfortable and wanted to go home consequently he was discharged and referred back to our dispensary

Methods of Study—For the total nitrogen determinations the Kjeldahl method was employed Ammonia estimations were made by the simple titration method potassium oxalate, formaldehyd and tenth normal sodium hydroxid being used These results were occasionally checked by the Folin aeration method Sugar was determined in the blood and urine by the methods of Benedict The carbon dioxid tension in the alveolar air were practically all made with the Fridericia instrument but an occasional determination was made with the Haldane apparatus Acetone and aceto acetic acid were estimated together by the method of Folin and Hart

COMMENT

1 The condition of absolute diabetes has been one of considerable interest since the pioneer work on the subject was recorded by Minkowski[5] This observer discovered that when the pancreas was completely removed from a dog whether the animal was fasted, fed with a diet of protein or on protein and fat that it would excrete 2 8 gm of sugar in the urine for each gram of nitrogen As the animal was glycogen free,

---

[5] Minkowski Arch f Exper Path u Pharmakol 1893 **31**, 85

and fat in no way affected the ratio, Minkowski concluded the sugar could come only from the protein. Other experimenters did not agree with the results of Minkowski at that time, as they claimed their results showed a variable D: N ratio. More recent observations, however, have largely confirmed the truth of Minkowski's work, showing that the maximum diabetes which can be produced from a complete pancreatectomy produces a dextrose to nitrogen ratio of 2.8: 1.

More recently Lusk and Stiles[6] (working with diabetes produced in animals by the subcutaneous injection of phlorizin) found that the ratio as established by Minkowski did not represent the maximum dextrose to nitrogen excretion which is obtainable. Phlorizin acts by mobilizing all sugar which is deposited as glycogen in the animal body, and causes it to be excreted through the kidney. Subsequently phlorizin is able to prevent any more sugar from being deposited in the tissues as glycogen. When an animal is being so treated, it rapidly becomes free from all deposited glycogen, and the sugar excretion strikes a constant ratio to the nitrogen output. This ratio was found to be 3.65 gm. of sugar to 1 gm. of nitrogen. As 6.25 gm. of protein (when completely utilized by the body) leaves a residue of 1 gm. of nitrogen to be excreted, it is apparent that there is available from 6.25 gm. of protein 3.65 gm. of sugar, or about 59 per cent. of the protein molecule is converted to sugar in the animal body.

These results were later confirmed by Mandel and Lusk,[7] working with severe human diabetes. Their patient was kept on a diet of fat and protein, and soon the urine showed 3.65 gm. of sugar to each gram of nitrogen. This condition existing in the diabetic was termed the "fatal ratio" by Lusk, as he believed no patient showing such a proportion of sugar output to nitrogen excretion could recover.

The Lusk dictum has generally held true until the establishment of the starvation treatment for diabetics. There were just two instances of absolute diabetics to my knowledge who were treated prior to the institution of starvation treatment and were apparently relieved by our previous methods. These two cases were reported by Foster[3] and Greenwald.[2] The subsequent course of their patients was not recorded. Up to two years ago the fact that only two cases of survival from complete diabetes were reported confirmed the truth of Lusk's dictum, under former methods of treatment.

Since the adoption of starvation treatment, however, Geyelin and Du Bois[4] reported one case of recovery from the "fatal ratio" with subsequent return to a fair degree of sugar tolerance. This case in many respects was very similar to that of the patient under discussion. In both instances the sugar tolerance was reduced in potential diabetics to approximately the least level by acute infections. The two showed return of sugar tolerance to approximately the same degree.

As indicated in the table, the patient whose case I have reported showed a dextrose to nitrogen ratio of 3.93: 1 on one instance and as low as 1.27: 1 on another instance. However, the average of dextrose to nitrogen excretion for the entire thirteen day period was 2.5: 1. On the two days on which he received 10 gm. of carbohydrate in the form of greens, it will be observed that the ratio dropped below 2: 1. I do not believe that the carbohydrate was converted to sugar in the patient because the greens appeared in the stool unchanged in a very brief period. If they were not utilized as sugar, the patient's ratio was 2.6: 1 on these two days, which would be quite consistent with the ratio on other days.

The results on these two days also give very good presumptive evidence that fat is not converted to sugar in the diabetic, for on both days the patient was supplied with 25 gm. of fat, and if it had been converted to sugar, the dextrose to nitrogen ratio should have been greater, whereas it was lower.

2. This patient showed a very great increase in nitrogen metabolism which persisted for the first nine days of his stay in the hospital. It will be noticed that on the tenth day the nitrogen excretion fell off very markedly and never at any later period showed an increase. On the second day of the test diet, however, when the patient was getting a very liberal supply of nitrogen in his food (16 gm. daily), he excreted 8 gm. in excess of his intake. This shows that he was using 50 gm. of his own body protein besides the amount which was taken in the diet. On the second day of starvation the nitrogen excretion was the greatest of any day while the patient was fasting. It was on this day that the patient's condition was at its worst, the tension of carbon dioxid reached its lowest point, and the acetone and diacetic acid excretions were the greatest for the starving period.

Excess nitrogen excretion has been observed many times in severe diabetes. Numerous authors have described cases which showed many times greater excretion than this patient. The most interesting thing, however, was the subsidence of the excess elimination of nitrogen in this patient when he was in the period of "fatal ratio." The causative factors of excess nitrogen excretion in the diabetic are not clear. It cannot be explained by the fact that the patient had an infection with fever. Both of the latter factors persisted long after the excess nitrogen excretion subsided. Neither can it be explained from the failure of this patient's body to utilize carbohydrate or from excess fat metabolism, for both of these conditions were constant during the period of excess nitrogen excretion and afterward.

Von Noorden[8] attributes excess protein metabolism in diabetes to some toxic substance which is retained in the body. It appears that such a possibility could have existed in this case. The few days of starvation which preceded the subsidence of excess nitrogen elimination might have been sufficient to allow the patient by some mechanism to eliminate a supposed toxic material.

3. The carbon dioxid tension of this patient was very low on admission, and it went down decidedly during the first two days of starvation. After the second day of starvation the tension gradually mounted and reached a perfectly normal figure by the time the "fatal ratio" had disappeared. It is also interesting to note that on the day the carbon dioxid tension reached the lowest level, the nitrogen, acetone and diacetic acid excretions were the greatest. These factors are doubtless related to each other. On the same day the patient's general condition was distinctly worse, he appeared toxic, his respiratory rate was 25 to the minute, and he was decidedly stuporous. There was grave fear that if starvation was continued the patient would go into coma. We considered terminating the fast and giving the patient more alkali. It was not

done, however, and on the following day the patient was in much better condition, and as the alveolar carbon dioxid tension had come up slightly, there was more encouragement to continue the fast From this time on the carbon dioxid tension gradually rose, and the patient's general condition was quite commensurate with it

4 The excretion of acetone bodies fell off markedly on the first day of starvation, and continued at a low level until the fast was terminated, and finally disappeared from the urine after the sugar tolerance was established Unfortunately, beta-oxybutyric acid determinations were not made in this case, but doubtless it follows the same course as its companions, by disappearing from the urine as the carbohydrate tolerance is gradually raised The reduction of these acid bodies *in the urine promptly with the institution of* starvation, has been one of the particularly illuminating points which has been brought out by our recent methods for the treatment of diabetics It will usually be found that there is a prompt reduction of the daily excretion of acetone, diacetic acid and beta-oxybutyric acid when the diabetic is cut off from the external supply of the precursors of these acid bodies, namely, fat and protein However, they will persist in the urines of these patients as long as they are living on a diet of fat and protein to the exclusion of carbohydrate food During starvation, of course, the only food the diabetic receives is that which is obtained from the body tissues, and since they are all largely glycogen free, it is apparent that they are living chiefly on a diet of fat and protein They will, then, of necessity excrete varying quantities of acid bodies This excretion of acetone, and diacetic and beta-oxybutyric acids will continue until such time when the patient is eating and assimilating enough carbohydrate food to prevent their formation The amount of carbohydrate necessary to prevent the formation of acid bodies varies with different patients In most patients 75 gm of carbohydrate are required to insure the complete combustion of fat and protein, but some diabetics have been observed whose urine remained free of these acid bodies to crude tests on 30 gm of carbohydrate daily

5 Another method which we formerly employed to determine the degree of acidosis was the ratio of ammonia excreted in the twenty-four hour urine to the total nitrogen output This case showed what in former times would have been considered an alarming figure, but it will be noticed that the same percentage was eliminated day after day, some time after the patient recovered from the acidosis, so far as the carbon dioxid tension was concerned Our former view in regard to the excretion of ammonia in acidosis as a protective mechanism is not tenable in the light of our present knowledge It will have to be explained on some other basis It certainly is of little service as an index to acidosis

6 This patient was starved eleven full days The only food taken during that time is enumerated in the table He had 180 c c of whisky daily, black coffee as desired, and on two days 10 gm of carbohydrate and 25 gm of fat This, I believe, is the longest period any patient has been starved to render the urine sugar free It might have been possible to make this patient's urine sugar free by alternate starvation days, but after all I think in this instance that fasting as employed was the safest and quickest method Had we delayed, doubtless the patient's infection would have advanced very rapidly, and perhaps the acidosis would have increased just enough to throw him into coma As it was, the sudden withdrawal of substances which were producing acid bodies in his system (namely, fat and protein) was sufficient to avert coma, and quite sufficient to allow him to recover from his acidosis before the fast was terminated

Diabetics of an extreme degree should never be starved without constant watch being kept on the tension of carbon dioxid in the alveolar air There is no satisfactory method for the measurement of acidosis aside from carbon dioxid determinations Methods requiring body excretions are inaccurate, and are usually not available when needed Carbon dioxid determinations can be quickly made, and will give instantly the condition of the patient These patients may go extremely acid with great suddenness

Irreparable harm may be done by such long starvation periods in the diabetic It may be the cause of lighting up an old tuberculous process, or so reduce the patient's nutrition that the body would be an easy prey to any infection But this question must be

Patient ate small amount of oatmeal that he took from another patient s tray settled by the exigencies of the case at hand Certainly this patient was not harmed

7 Another curious thing about this case[1] was the fact that the scales did not show that he lost any weight during the entire starvation period There are great variations in these daily weights I have no means of proof as to their accuracy, as they were taken as a matter of routine in the ward, but I believe they are correct I think the fact that he did not lose weight can be accounted for on the basis of water retention It was on the day of January 28 that the patient gained 2½ pounds This was also the day the patient became sugar free We all noticed on the following day that the patient looked edematous He did not have an edema, but there certainly was an increase to the volume of his body Previously his face had been drawn and shrunken, but on this day his face was full and gave the impression of a decided gain in weight

Since the patient's discharge from the hospital he has been seen only occasionally His condition had been variable Certainly he is not any worse than he has been for the last year or two He is a very unsatisfactory individual to manage, never being willing to cooperate except in one's presence

SUMMARY

1 In the case reported, the sugar tolerance of a patient with a potential diabetes was reduced to approximately the least level for thirteen days by an acute infection Later the patient had return of a moderate degree of ability to utilize carbohydrate

2 There was a great increase in nitrogen excretion for the first nine days, on the tenth day it fell off decidedly, and never was again excreted in excess

3 The patient was distinctly acid on admission, but became decidedly more acid during the first two days of starvation, as shown by determinations of the tension of carbon dioxid in the alveolar air Although the patient was starved for eleven days, the acidosis gradually became less and less each day, until by the end of the fast the tension of carbon dioxid was back to practically a normal figure

4 Acetone and diacetic acid excretion dropped very decidedly during the first day of starvation, and completely disappeared from the urine when the patient was utilizing 60 gm of carbohydrate daily

5 The patient was excreting approximately 30 per cent of nitrogen in the form of ammonia during the period when he was most acid, as the acidosis improved, the percentage of ammonia to the total nitrogen output remained the same

6 The body weight of the patient was practically the same at the termination of the starvation period as it was in the beginning

Moving Picture Health Car—In North Carolina the state board of health has an automobile fully equipped with a light and moving-picture outfit, with which moving picture health shows are given throughout the state in cities and towns, at county fairs and other gatherings, in churches, halls, tents or out of doors Any series of twelve towns may have the benefit of the outfit, which is provided with a mechanician and a lecturer, for a period of three weeks, the show being given in each town one afternoon or evening of each week, and the program being changed each week The towns are required to provide at least $90 for the expenses of the first week, and the remainder is furnished by the state board The subjects are not all health topics, but comic or other pictures are interspersed The entertainments are popular and their educational value is said to be high

---

ANKYLOSIS OF THE JAWS*

CHALMERS J LYONS, D D Sc
ANN ARBOR, MICH

In his work on orthroplastics of the temperomandibular articulation, Murphy classified the ankylosis which occurs in and about the temporomandibular articulation under four heads (1) intra-articular bony ankylosis, (2) intra-articular fibrous ankylosis, (3) subzygomatic cicatricial fixations, and (4) intra-alveolar buccal fixations

The only part of this subject which I shall consider at this time is the first division of Murphy's classification, intra-articular bony ankylosis, or true ankylosis While this affection is not rare, there have been comparatively few actual cases with results reported, and the work done along this line, and reported in medical or dental literature, is by no means extensive

For the purpose of clearer statement, let us review briefly the temporomandibular joint Owing to the character and location of this joint, it is particularly susceptible to traumatism and infection When the complex mechanism and environment of this joint is considered, it can readily be seen that an injury, or an infection in it, or a combination of the two, is far from being amenable to normal repair[1] In the temporomandibular articulation, the socket is formed partly by the mandibular fossa and partly by the articular eminence, and over the latter, an approximately congruent surface for the head of the condyle is formed by the articular disk The two temporomandibular articulations act simultaneously When the mouth is opened, the head of the condyle with the interarticular disk glides forward on the articular eminence, and when the mouth is closed, it slips back into the mandibular fossa The opening and closing of the mouth are consequently attended by a sliding of the mandible (a gliding joint) In addition to this modified form of hinge movement, the articulation possesses a second kind of motion, viz, the lateral displacement of the mandible in reference to the skull In this movement, one condyloid head remains in the mandibular fossa, and rotates or pivots on a center, while the other advances on the articular eminence, a movement which is impossible when the mouth is opened to its greatest extent Both the hinge and lateral movements are combined in the act of mastication Thus an inquiry or an infection involving this joint is much more complex than the same lesion would be involving a joint less intricate, and the process of repair is consequently much more complicated

ETIOLOGY

What causes intra-articular bony ankylosis of the jaw? The two sexes are about equally affected, and this seems to be an affection into which sex selection has no controlling influence

It has been my own observation, as well as that of others, that the predisposing age is from 1 to 10 years, that is, that the largest percentage of patients who come under our observation present a history of injury or infection in the early ages Orlow found that ankylosis was established in 80 per cent of his patients between the ages of 1 and 10 years. Blair states that "the age at which ankylosis became established varied considerably, but in the great majority of cases, when the age was given, it was under 10 years." The primary causes for ostearthritis, or bony ankylosis, seem to be traumatism and infection. There seems to be some diversity of opinion as to which of these etiologic factors should be assigned first place. Orlow states that in about 30 per cent of his cases, injury to the joint was the cause of bony ankylosis. Blair asserts that "by far the most common single cause was trauma, this accounting for nearly 50 per cent of all cases. The great majority of these injuries were not open wounds, and by far the most common form of injury was a blow, or a fall on the chin." Others believe that infection is the greatest etiologic factor in the affection, and some believe that in every case of trauma which seems to cause ankylosis, infection is a secondary factor of no mean importance.

---

* Read before the Section on Stomatology at the Sixty Seventh Annual Session of the American Medical Association Detroit, June, 1916

[1] Sobotta and McMurrich Human Anatomy, W B Saunders Company

My own observation has been that trauma has been at least the primary cause in by far the largest number of cases presented in our clinic. Authentic statistics in this regard cannot be procured readily, owing to the fact that the large majority of these patients are not seen until long after the condition is established. Sometimes several years elapse before surgical interference is resorted to, so that a complete history in such cases is not wholly reliable. The diseases which play a part in causing ankylosis of the jaws are scarlet fever, otitis media, dento-alveolar abscesses, diphtheria and gonorrhea. It may also result from a metastasis, from foci of infection within the mouth, or elsewhere in the body. The presence of the beginning of ankylosis of the mandible during childhood appears logical when we consider that accidents and many of the infectious diseases to which it is due are more prevalent during the early period of life. The onset and development of ankylosis of the jaws is very insidious and slow, several years often being occupied in the production of lesions of any considerable extent. Usually the patients complain more of the disability which is caused by the affection than of any actual physical discomfort which it occasions. The general health of patients who are afflicted is usually little impaired. Digestive troubles seem to be the principal factors outside of the joint lesion, owing, undoubtedly, to the impaired function of mastication.

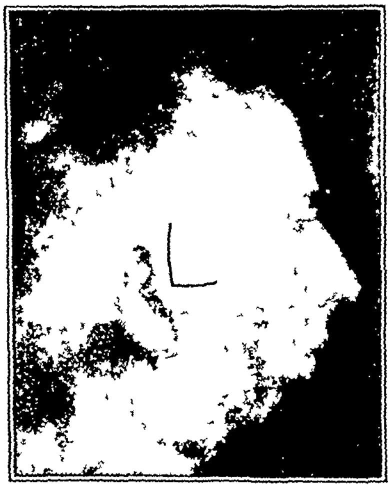

Fig 1.—Course of the incision.

PATHOLOGY

In case of violent injury to the joint, ankylosis is usually brought about by the proliferation of fibrous tissue into or around the region of injury.

Should the articular cartilages be preserved in whole or in part, they sometimes undergo direct metaplasia into fibrous tissue or fibrocartilage, or into mucinous tissue, which gradually becomes fibrous. In many of these cases the fibrous tissue is trifling in amount, and the ankylosis is produced mainly by cartilage and bone. In some cases the ankylosis is due to cartilage and bone intermingled. Immediately following a dislocation or intracapsular fracture, or a contused wound to the joint, there is more or less abundant hemorrhage into the joint. Later, inflammation sets in. The capsule and surrounding parts become swollen and edematous, infiltrated with inflammatory products. There is an effusion into the synovial cavity. Portions of the coagulum may persist and become organized, forming osseous tissue in the joint. When an infection is the predominating etiologic factor, there is produced a synovitis with effusions into the joint cavity. These infections may be purulent, and chronic synovitis results. The joint synovium becomes thickened in the early stages, while the surface of the cartilage is rough and fibrillated. Marked inflammatory changes are induced in the subcartilaginous marrow spaces and the cartilage is destroyed. Milen believes that the degeneration of the cartilage is due to some interference with nutrition, or is produced by the extension of the exudate which destroys the cartilage. Adami[2] states that the resorption of the cartilage is brought about by the subchondral medullary substance. In the early stages not all of the cartilage may be destroyed, but there may remain islets of cartilage throughout the articulating surfaces. These islets may in time be converted into bone.

Thus the cartilages are gradually transformed into a vascular fibrous or fibro-osseous tissue. The joint cavity is traversed by dense fibrous bands, and is converted into a number of small spaces, bounded by dense fibrous tissue, and containing synovial fluid. In the advanced stages, the whole of the articular cartilages may disappear and be replaced by fibrous tissue, so that the original structure of the joint becomes well nigh unrecognizable. Secondarily, changes take place in the newly formed fibrous tissue, and in time it is converted into a mass of spongy bone, and complete osseous ankylosis results. It seems to be a characteristic phenomenon of cartilage that it is more or less interchangeable with fibrous tissue in the joints. It has been observed that when a joint cartilage is becoming atrophied, it becomes calcified, or transformed into a fibrillated structure, closely resembling fibrous tissue, while perichondrial fibrous tissue commonly becomes changed into typical hyaline cartilage. The deeper layers of the cartilage may also proliferate, forming nodules of hyaline cartilage or bone.

The greatest metaplasia, however, is found in subcartilaginous inflammatory process, where, as a rule, there is a great tendency to the formation of cartilage and bone. Thus, in an inflammatory condition of the temporomandibular articulation, either by traumatism or by infection, there is a marked susceptibility to metaplasia, with the result that the normal structure finally may become obliterated and a new structure results.

Characteristics of the Disease.—On account of this disease occurring in the joint, and having its incipiency in early childhood during the period of growth, the normal development of the mandible is considerably interfered with, so much so that it is marked by a conspicuous facial deformity. This deformity is characterized by perceptible recession of the chin This may be due to the action of the geniohyoglossus muscles in their constant efforts to open the jaws There is also a general atrophy from disuse of all the tissues of the lower jaw, including the mentalis and quadratus labii inferioris muscles The deformity may be so exaggerated as almost entirely to obliterate the chin Usually when the ankylosis has been established on one side in early childhood by trauma, and the disease has slowly progressed until the normal structure of the joint has become obliterated and the jaws closed, the opposite side also will be more or less affected on account of the disuse of the joint

---

DIAGNOSIS AND TREATMENT

The differential diagnosis in the character of the ankylosis is not a complex problem In fibrous ankylosis, even though the adhesion is quite firm, there will be some movement, especially lateral movement in the jaws In bony ankylosis, the only movement which can be observed is the very limited movement of the elasticity of the structures involved There can be no lateral movement in the lower jaw in intra-articular bony ankylosis

The treatment of intra-articular bony ankylosis consists in surgical measures Forced separation of the jaws will avail nothing The surgical procedure consists in establishing pseudarthrosis, either in the site of the true joint or below it Esmarch, in 1855, suggested an operation for intra-articular bony ankylosis by the removal of a wedge shaped section of bone, with base downward, three-quarters inch long, from the horizontal portion of the mandible This did not prove satisfactory on account of the disturbance of the normal action of the masticatory muscles which followed Konig, in 1878, introduced the operation of resection of the mandibular head The results were unsatisfactory on account of the possibility of a recurrence

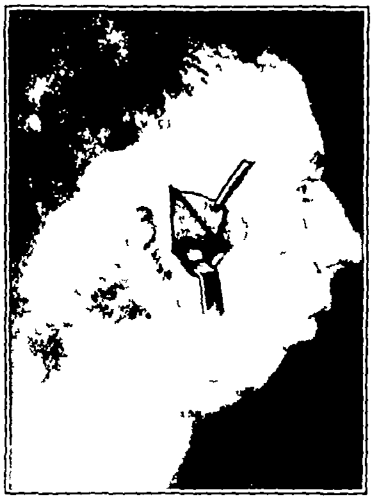

Fig 2—Exposure of the joint.

Brophy[3] states that he has obtained very satisfactory results by removing a crescent shaped section of bone from the region of the angle of the jaw He places gutta percha between the ends of the bones which prevents the freshened ends of the bones from uniting The gutta percha is allowed to remain for a period of six weeks, after which the wound is reopened and it is removed During this time, it is asserted that a well organized membrane is formed which seems to form the intra-articular tissue

The operation which has been very satisfactory in my experience is the operation similar to the one reported by Lilienthal,[4] in which a section of bone is removed from the condyle

Technic of the Operation—Beginning about 5 mm in front of the tragus of the ear, a horizontal incision is made through the epidermis and superficial fascia along the lower border of the zygoma, extending anteriorly for a distance of about 3 cm A vertical incision is then made through the epidermis and superficial fascia, extending upward from the point of beginning about 4 cm, running just in front of, and parallel to the ear (Fig 1) The epidermis and superficial fascia are now dissected up to form a flap The underlying tissues containing the branches of the seventh nerve and also the superficial vessels are pushed aside by the use of retractors and blunt dissectors until the joint and a portion of the condyle is laid bare (Fig 2) Great care must here be exercised that the zygomatic and temporal rami of the facial nerve are not torn in the effort to expose the bone

After the neck of the condyle has been cleared of the tissues by blunt dissection, a full curved aneurysm needle is used for the purpose of guiding a steel ribbon $^{3}/_{1000}$ inch in thickness and 1 cm in width, back under the condyloid neck (Fig 3) This is for the protection of the internal maxillary artery in removing the section of the condyle The section is removed by the use of the mastoid chisel, taking out about 1 cm of the bone, including the periosteum Then a flap of superficial fascia is elevated from the temporal muscle and interposed between the ends of the condyle, and sutured with catgut sutures The wound is then closed with horsehair

After the excision of a portion of the condyle, as indicated, has been accomplished, on one side, an attempt should be made to open the mouth If the jaws cannot be opened, the same operation should be resorted to on the opposite side, when of course the jaws will be free No attempts should be made to stretch the jaws or hold the mouth open until partial repair of the soft tissues has been obtained After about the fifth day, my treatment has been to begin opening the mouth by the use of a graduated mouth gag The patient will experience considerable pain at first, but the mouth should be opened until there is at least a space of 2 cm between the opposing cuspid teeth When this space is obtained, the graduations on the gag are noted and the gag placed in the same position in the mouth and opened to the same degree, four or five times each day Each time the gag is inserted, it is left in position for a period of five minutes This treatment of stretching the jaws should be maintained for several weeks, the patient doing this himself, after being properly instructed

Dangers, Disadvantages and Complications of the Operation—One of the greatest dangers involved in the operation is that of infection Owing to the close proximity to the hair line, there is a greater possibility of infection either in the wound at the time of operation, or subsequently, than in wounds of like nature elsewhere on the skin surfaces Therefore the greatest precautions must be exercised that everything connected with the operation should be absolutely sterile and that extra precautions be taken in the subsequent dressings of the wound, that infection be warded off An infection in the wound may ruin what would otherwise be a successful operation

Necessarily after repair has taken place, there is more or less cicatricial tissue at the point of operation, which leaves a scar and sometimes more or less of a depression at the point of the false joint, but this, in my opinion, is of secondary importance The dangers

---

[3] Brophy Oral Surgery the Diseases Injuries and Malformations of the Mouth and Associated Parts Philadelphia, P Blakiston's Son & Co

[4] Lilienthal Ann Surg, August, 1911

to be encountered in the operation are, first, the inability of the anesthetist to control the tongue during the administration of the anesthetic Some cases are on record in which tracheotomy had to be resorted to during the operation Second, danger of injury to the temporal rami of the seventh nerve, whereby paralysis of the orbicularis oculi muscles may follow Another danger to be encountered is injury to the internal maxillary artery This vessel lies directly in the field of operation, and must be protected in some manner in removing the segment of bone in the process of forming the new or false joint This may be accomplished by retractors, Murphy's periosteotomes, or any other instruments which may be easily inserted between the artery and the neck of the condyle I believe that the steel ribbon which I have described is superior in the simplicity of its application, and effectiveness, to anything which has been called to my attention

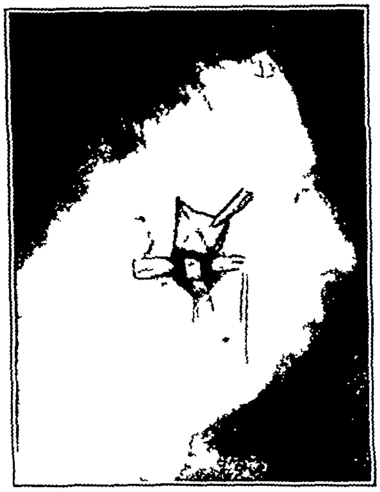

Fig 3—Insertion of steel ribbon

CONCLUSION

It might be stated that, outside of the dangers enumerated, this operation is comparatively free from serious complications or sequelae The patient begins the mastication of his food in about ten days to two weeks following this operation The movement of the jaws prevents the formation of too much fibrous tissue between the two ends of the bone, and after repair is completed, it will be found that the tissue which had become atrophied begins to take on a more nearly normal condition The patient takes on weight, the general health and appearance improve and he again resumes confidence in himself The correction of ankylosis of the temporomandibular articulation is an operation which not only gives great satisfaction to the patient, but also is one which is very gratifying to the operator

ABSTRACT OF DISCUSSION

Dr H A Potts, Chicago These results of injuries and infections are really more common than the general practitioner seems to think Quite frequently we see, in large clinics, patients who present the same appearance as this one The diagnosis as to the form of ankylosis is very important, and judging from the experience of previous operators and the conditions found at operation the operation here described is certainly of the type which is best suited to the bony ankylosis The dissection of fibrous bands and the treatment of the various classifications as given would permit of other treatment but the bony ankylosis is best treated Dr Lyons is to be congratulated on the result in this case which if the patient does his part will avoid a further complication or even lessening of the space already gained

Dr Chalmers J Lyons, Ann Arbor, Mich Of course in these cases the patients must do their part They are instructed to keep constantly stretching the jaws These instructions are very important More can be accomplished by this stretching than by anything else, doing it several times a day, to keep the space already gained This man has gained a little more space by this exercise

Dr Potts If you put the index finger on the upper teeth and the thumb on the lower teeth, you can get a good deal of force in stretching

Dr Lyons That is a good suggestion These exercises must be kept up continuously In these cases, if nothing is done, there is a great tendency for the ankylosis to recur

CALCIFIED HEMATOMA *

FREDERICK C KIDNER, M D
Fellow of the American College of Surgeons
DETROIT

Interest in the occasional development of bone masses in and beneath muscle following trauma has been great, especially since the Roentgen ray has made possible their clear demonstration The condition has commonly gone under the name of myositis ossificans traumatica, because it has been believed that damaged muscle is actually changed into bone Other names have been suggested depending on various theories of origin, for example, calcified hematoma, based on the theory that the blood clot following an injury becomes calcified, and periosteal callus, on the theory that the growth is merely misdirected callus formation The best known theories so far put forward are, first, the hemic theory (Sadeler) This theory supposes that the hemorrhage following an injury to muscle is first transformed into cartilage which later ossifies Second, that the tumors are aberrant sesamoid bones (Bard) Third, the theory that the growths result from bits of periosteum detached and included in the muscle Fourth, that the fibrous tissue of the muscle undergoes a true metaplasia into bone Fifth, that the bone develops from cells disseminated from the periosteum through the hemorrhage All these theories have warm supporters and antagonists

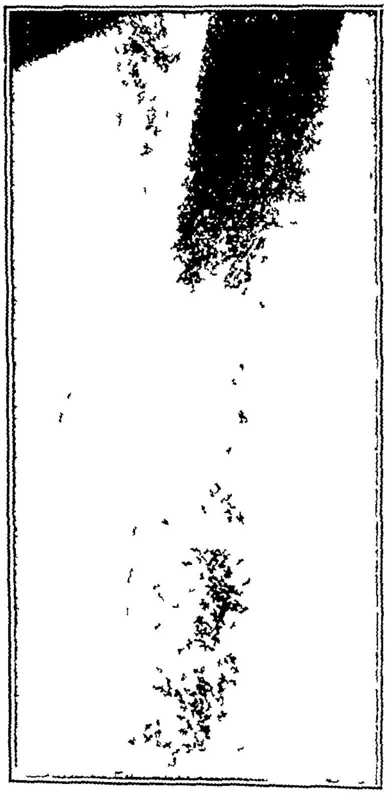

Fig 1—Before operation

The best discussion which has come to my attention of the surgical and pathologic aspects of this condition

---

* Read before the Section on Orthopedic Surgery at the Sixty Seventh Annual Session of the American Medical Association Detroit, June 1916

is that published by Fay[1] He favors the combination theory in which both the periosteum and the fibrous tissue of the muscles take part

Much of the confusion as to the origin of these growths is due to the fact that sometimes the bone mass is attached to the periosteum, and that sometimes it lies within the muscles without periosteal connection, most commonly in the brachialis anticus or the quadriceps This difficulty is easily overcome by the assumption, which I believe to be a reasonable one, that there is always, at some time, a direct connection with periosteum which may or may not be absorbed or broken off by muscular action In support of this assumption is Coley's[2] statement that recurrence can best be avoided by covering the periosteum with a fascial graft

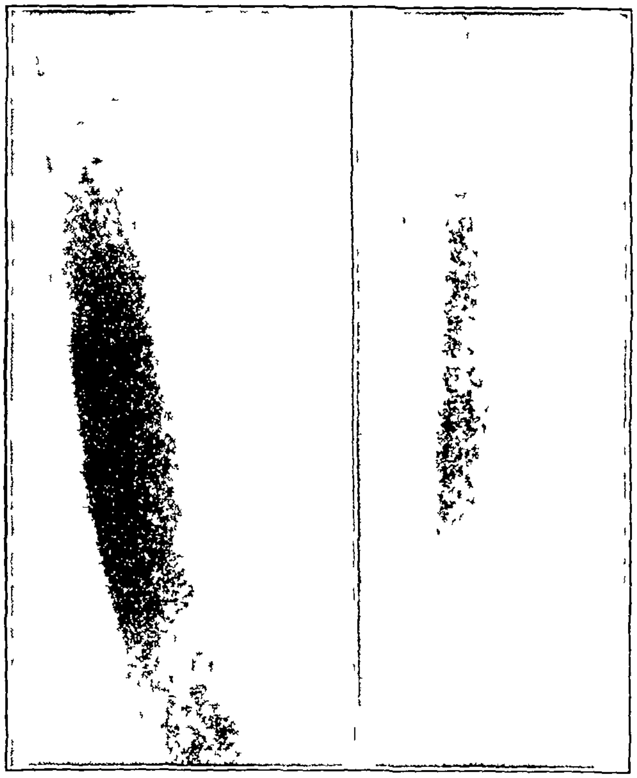

Fig 2 —Present time

The following case aroused my interest in the subject, and is, I believe, worth reporting in the hope of shedding a little more light on the causation of the condition

W B, vigorous schoolboy, aged 16, was without disease or family taint Five weeks before he was seen, March 21, 1916 he was kicked on the front of the thigh during a basketball game There was immediate pain and stiffness, but he continued the game Next day pain was rather severe and he was forced to limp Pain gradually passed off but the stiffness did not decrease, and for the past two weeks had been increasing Examination showed a slightly tender, hard mass involving the middle third of the front of the thigh The muscles moved over it to a certain extent, but flexion of the knee was possible to only about 15 degrees, a severe pulling sensation preventing further motion Probable diagnosis of calcified hematoma was made Roentgenograms taken at the time showed a long mass with the character of bone, lying close to the front of the femur, to which it was attached at one point

The possibility that the mass was sarcomatous made exploratory operation advisable This was done, March 22 An incision, just in front of the iliotibial band, at the outer side of the growth, was carried through the fascia lata, and the muscles separated by blunt dissection A mass of vascular new bone was found, surrounding the anterior half of the middle third of the femur Anteriorly it was firmly adherent to the vastus medius by many torn and partially destroyed muscle fibers which issued from the bone substance These anterior attachments were easily separated and the bone found to be firmly adherent, at about its middle, to the surface of the femur With considerable difficulty the mass was pried loose and removed At the point of adhesion to the femur was found an area one-half inch in diameter, where the bone was denuded of periosteum The perimeter of this denuded area was made up of much thickened and edematous vascular periosteum with ragged edges The thickening gradually decreased in all directions for a distance of three-quarters inch, at which point the periosteum became normal

Feeling convinced that the mass originated from the periosteum at this point, the denuded area and the edges of the thickened periosteum were carefully covered with bone wax in the hope of preventing further overgrowth The specimen was sent to Dr C R Meloy of Grace Hospital to whom I am indebted for the microscopic slides The patient made an uneventful operative recovery and was about in ten days Two weeks later he had about 45 degrees of motion in the knee and was rapidly gaining more motion At that time he sustained a severe wrench, whereupon the stiffness promptly reappeared, and there was very marked induration of the deep tissues of the front of the thigh, which closely resembled the original growth Since, this has gradually disappeared and motion is constantly increasing The roentgenograms taken at present show that the growth has been stopped and that the remains of it are absorbing The microscopic sections taken from various parts of the new bone are of

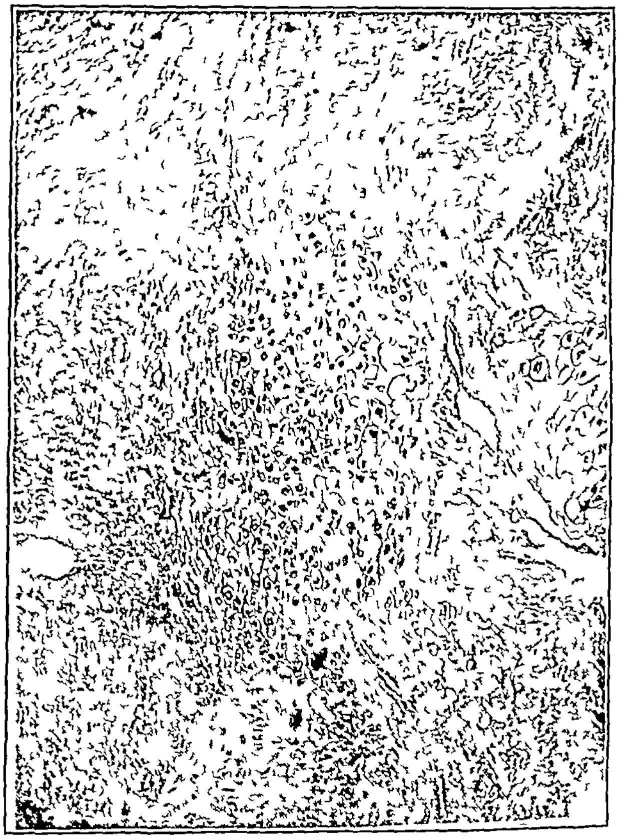

Fig 3 —Cartilage formation

---

[1] Fay, O J Parosteal Callus, the So Called Myositis Ossificans Traumatica Tr West Surg Assn 1913 p 174

[2] Coley, W B Myositis Ossificans Traumatica, Ann Surg, 57, 305

extreme interest, in that they show all stages of bone formation The whole mass is surrounded by a fibrous tissue capsule, in the meshes of which can be seen partially destroyed muscle fibers These are scattered all through the growth From this capsule cartilage is growing, as is bone There are areas of transformation of cartilage into bone, and areas of fibrous tissue undergoing myxomatous change with a substitution of cartilage cells, evidently a direct change in cell character The picture therefore, is that of callus formation originating in the periosteum Everywhere the picture is that of muscle destroyed by an invading growth, rather than muscle changing into bone The muscle bundles are evidently infiltrated and destroyed not actually forming new tissue

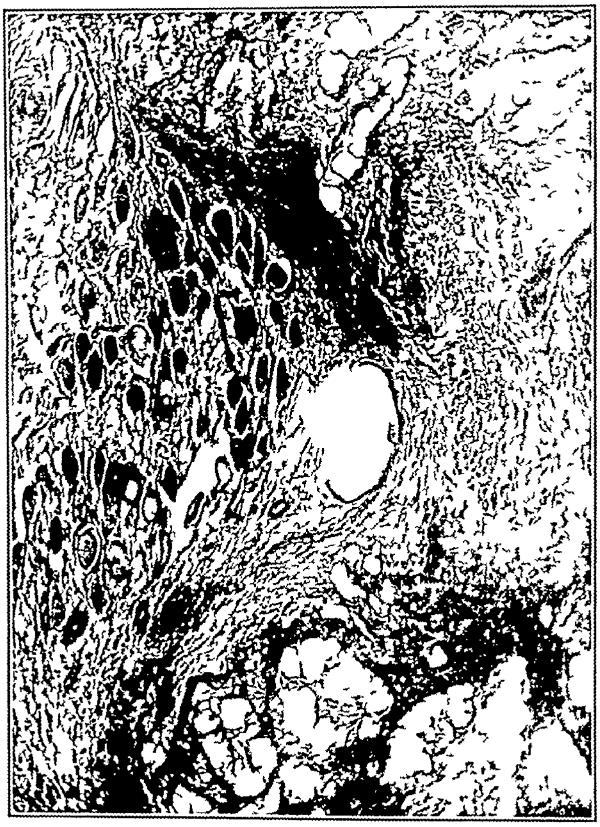

Fig 4 —Muscle surrounded by bone and fibrous tissue growth

Clinically this case is an example of successful operation for the removal of a large and necessarily disabling bone growth The failure to recur I believe to be largely dependent on the use of the protective film of bone wax at the point of periosteal injury Pathologically I believe the course of events to have been something as follows The original traumatism tore deep muscle fibers, and at the same time caused a break in the periosteum From both sources blood was poured out, and immediately deeper layers of periosteum responded to the stimulus of trauma by pouring forth osteoblasts These were free to wander through the mass of hemorrhage, which, in this case occupied only the deepest layers of muscle tissue A delimiting fibrous tissue membrane was formed by the intramuscular fibrous tissue as a preparatory step to the absorption of the blood clot On this membrane and its meshes were deposited the free bone-forming cells, and from all directions bone growths began Had the hemorrhage lain deeper in the body of the muscle or had the tear in the periosteum been smaller, it is easy to see how the connection between the two might have been obliterated within a very short time, and the bone growth have become entirely enclosed within the muscle body Had this occurred, Roentgen rays would have at no time shown connection between the growth and the periosteum, because the connection would have been severed before sufficient calcium was deposited to throw a shadow

Although I realize that the evidence of this case is far from conclusive, its presentation is justified on two grounds, first, because the apparent course of events is so plain and easy to understand, and second, because the theory which it seems to substantiate is a simple one Metaplasia of one tissue into another, even under extraordinary stimuli, is a difficult conception Overproduction of the tissue from its usual source is a simple one

David Whitney Building

ABSTRACT OF DISCUSSION

DR W C CAMPBELL, Memphis I have had two similar cases both of which were infected The first case occurred in a young boy, 9 years of age, who was referred to me for tuberculosis of the hip The roentgenograms showed a ring of bone in the region of the lesser trochanter Stereoscopic roentgenograms showed this ring of dense bone, about the size of half a dollar to be posterior and slightly external to the lesser trochanter and not connected with it in any way There was a sinus running from just below the greater trochanter tortuously through the thigh at the level of the lesser trochanter, opening internally in the perineum Bismuth injection of the sinus brought it out quite clearly I found at operation that there was no connection whatever with the bone There was no erosion, and the periosteum was intact but the condition was of two years' duration, and had followed an injury The result was complete cure, with no recurrence

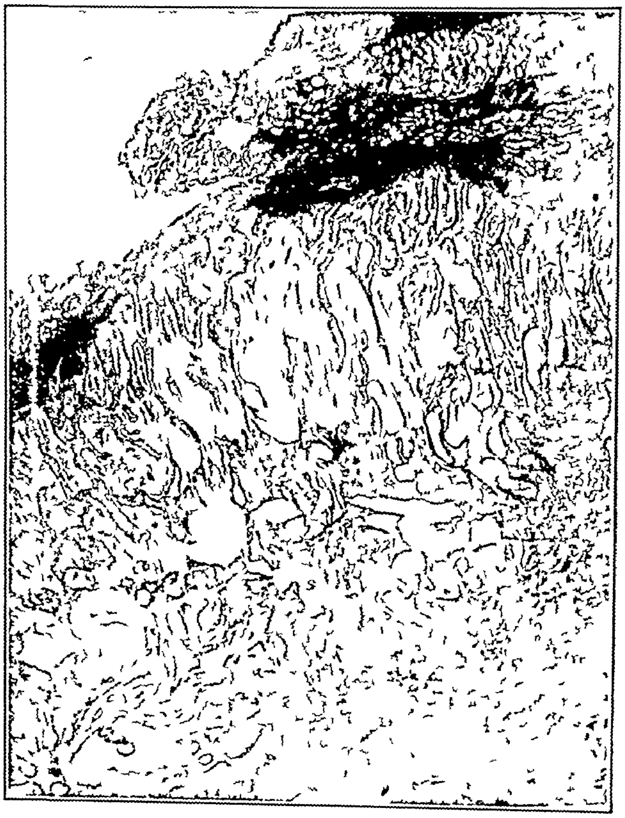

Fig 5 —Bone growing from capsule

after two years The second case was that of a man, aged 30, who gave no history of injury This case was also referred with an erroneous diagnosis of tuberculous knee The knee was red and fluctuating Operation showed an irregular mass anterior to the femur, just above the knee joint The mass was easily removed, and the patient made an uneventful recovery, except that the knee was involved and required further work Microscopically the mass removed was bone and not calcium deposits, as frequently occur in suppurating areas These cases were interesting, because both were infected, one with a sinus, and the other having no sinus

Dr James T Watkins, San Francisco I operated on a youth, aged 16, who, while playing football, had received a kick on the external aspect of the lower end of the thigh He was not more than temporarily discommoded, but later noticed at the site of injury a lump which was painless, but gradually increasing in size He wanted to enter the Naval Academy, but had been told that this deformation would exclude him For this reason he wished it removed So I cut down on the femur and chipped the mass off The muscle was not particularly adherent to it It did not occur to me to cover the cut surfaces as Dr Kidner did so as to prevent a recurrence However, there was no recurrence Microscopically it looked more like cartilage than bone The pathologist reported it to be a mixed cartilage and bone tumor and of a benign nature

Dr J D Griffith Kansas City, Mo These growths occur not only connected with those parts of the body where bones or periosteum are, but also elsewhere On two different occasions I have taken such a growth out of the abdominal muscles These specimens gave the evidence of bone structure My cases seem to show that in all instances the growth is not periosteal

Dr Frederick C Kidner, Detroit In regard to the question of origin of the bone in these unusual growths, I would say that I limited my paper to the purely traumatic cases following on severe injuries Such cases as Dr Campbell mentioned are very often the result of an infection, and the masses consist of calcium deposits, rather than bone I should like to know whether the masses were examined in Dr Campbell's cases

Dr Campbell Yes They were both necrotic bone, and the condition followed injury in one instance

Dr Kidner The element of chronic infection and of irritation enters here, and it is easy to conceive that the periosteum might be healed after the bone mass was formed In regard to the masses in other places, where there is no bone near, I do not think that we know much about them I am not willing to advance any theory on that subject

---

Influence of Caffein on Toxicity of Morphin Sulphate—From results recently obtained in experiments on cats and guinea-pigs by C C Haskell and A B Siewers (*Virginia Medical Semi-Monthly*, Dec 8, 1916), it would appear that the employment of large doses of caffein is not devoid of actual danger, and instead of lessening the toxicity of morphin sulphate, really renders the chance of the animal's recovery less probable They do not urge these results as evidence that caffein should not be used in the treatment of poisoning by morphin sulphate or other opium preparations, but that some limit should be placed on the amount of caffein used in the treatment of opium poisoning and that more attention should be paid to removing the unabsorbed morphin and hastening the elimination of that present in the circulation

A CLINICOPATHOLOGIC STUDY OF EARLY MALIGNANT CONDITIONS OF THE FACE AND MOUTH[*]

JOHN W MEANS, DDS, MD
AND
JONATHAN FORMAN, AB, MD
Instructor in Surgery and Instructor in Pathology respectively
Ohio State University College of Medicine
COLUMBUS, OHIO

The great latitude accorded the term "precancerous" has led to its application to a variety of lesions both cancerous and noncancerous For the sake of clearness in thinking it would be well to keep separate those lesions which may ultimately terminate in cancer from those cases which have recently assumed definite malignancy It is of the greatest importance to the patient, however, that a malignant condition be eradicated completely while it is still a local process

The majority of so-called precancerous lesions represent an incomplete or perverted reaction to some form of chronic irritation When the cells of any tissue are injured or destroyed there is an attempt at repair, and the neighboring cells are stimulated to reproduction Normally the development of these cells goes on at a rate equal to or greater than that of the most malignant of tumors, and they soon reach maturity In some cases, however, because of an influence of which as yet we know but little, these cells do not reach maturity but persist in a partially developed state and continue the process of reproduction far beyond the normal limits Thus a group of cells are formed which are not coordinated and correlated with the normal growth processes but are more or less independent of them To these the term "cancer" is applied

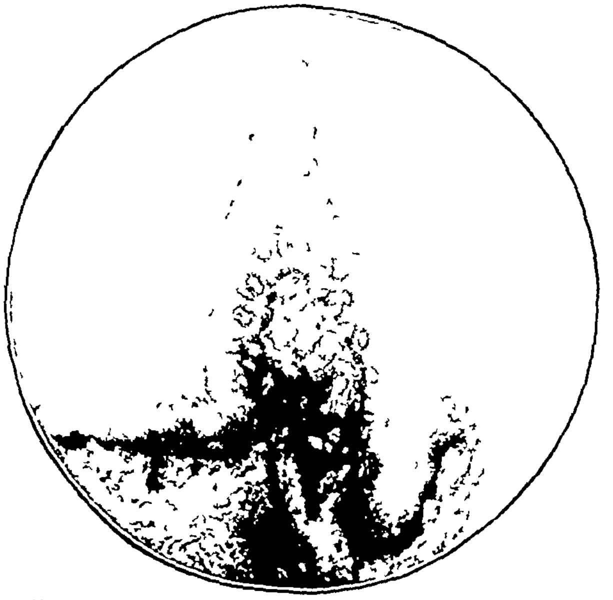

Fig 1—A small papillomatous growth occurring in the mucous membrane of the cheek opposite a jagged tooth in a man aged 50

About the face and mouth, carcinoma arises from one of three types of cell

1 The squamous epithelium of the skin and mucous membrane, giving rise to the epidermoid carcinoma or epithelioma

2 The cell of the hair follicle, giving rise to the hair matrix carcinoma or the often erroneously called basal cell carcinoma

3 The epithelium of the glands associated with the skin and mucous membrane, giving rise to the various types of glandular carcinoma

The most frequent tumor of this region is the epidermoid or squamous cell carcinoma The patients bearing this type of tumor give a history of having some form of lesion preceding the development of the cancer The smoker's burn is one of the frequent initial lesions described by these patients A small blister occurs which may disappear and reform again The histopathology of such burns has been so accurately and completely described by Bloodgood[1] that it will not be discussed at this time

---

[*] Read before the Section on Stomatology at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

In the order of frequency, the next "precancerous" lesion occurs as the result of mild traumatism repeated frequently over long periods of time The irritation of a jagged tooth, or in many patients the habit of holding nails, screws, etc, in the mouth can be discovered in taking the history Other lesions in which carcinoma develops are fever blisters, cracks, fissures, cuts which have refused to heal under ordinary care, papillomas and areas of leukoplakia The last lesion would appear to be a very important one when cancer of the tongue is under consideration, as each of the patients in the seven cases in this series gave a description of the initial lesion as a thickened, hard area on the tongue

While the history of traumatism can be elicited in the majority of cancer cases of this region, and especially those of the lip, there are many lips which have been injured in a similar way and which do not develop cancer In the last eighteen months we have seen two smokers' burns which, after persisting for a couple of months, disappeared and have not returned, and a sore developing in a fever blister which existed for nearly three months and then went away Whether these will return and malignancy develop in them, of course, cannot be said It would appear, however, that there is at work in the development of cancer some factor or factors other than simple injury

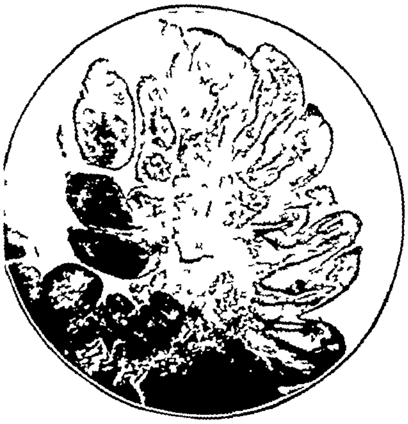

Fig 2—A papilloma on the tongue in a woman aged 27 There was recurrence because of incomplete removal Second excision successful

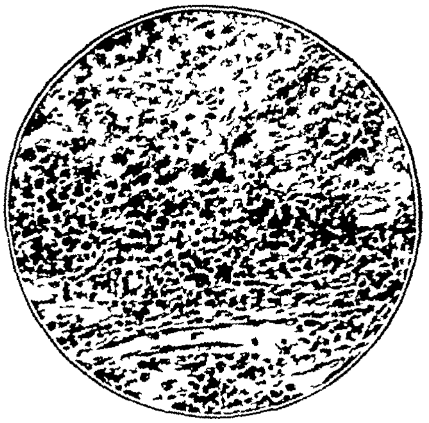

Fig 3—Both an exudative (lymphoid in character) and a proliferative reaction are shown about the invading tumor cells From a specimen of early epidermoid carcinoma of the lower lip

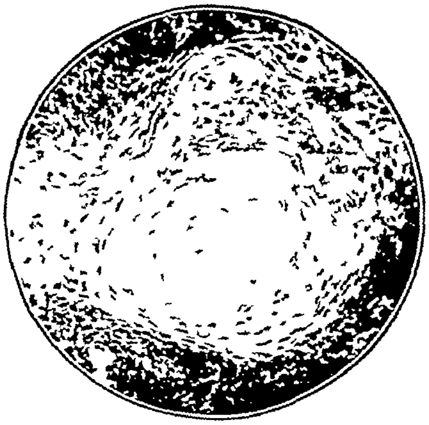

Fig 4—A group of metastatic cells in a lymph node of the neck associated with an epidermoid carcinoma of the lower lip which began in a razor cut Radical operation with no recurrence at the end of the third year Note the cornified mass to which the tumor cells are being reduced

Injuries of the types described do apparently determine the location of the cancer in those individuals in which these other factors are operative Of interest in this connection is the work of Miss Slye[2] She reports that cancer of the oral region is not frequent in mice, even in those strains in which the majority die with cancer Injury to these parts is also infrequent in these animals, whereas it is common in man

These conditions may persist without visible change for some time, but more often they gradually spread and break down, forming an ulcer This is usually of an irregular shape, having rather indurated edges which are not undermined The base is smooth and grayish There is often a thin, irritating discharge Around the edges is a zone of bluish discoloration containing blood vessels This is a picture of a fully established cancer Its persistency is a significant warning, and when such a lesion is found about the face or mouth in a patient over 35 years of age, it should be removed quickly Too much emphasis should not be placed on the age, for each case is more or less a law unto itself For instance, we recently studied a case of carcinoma of the tongue which began in the twenty-seventh year of the woman's life

In the twenty-two carcinomas of the face occurring above the line of the lower lip in the series which forms the basis of this study, twelve were of the hair matrix variety In larger series the proportion of this type is usually greater These tumors take their origin from the cells comprising the hair follicle They usually begin as a subcutaneous nodule After persisting for a variable period they break down and ulcerate They present a tendency to infiltrate widely but not deeply, and seldom produce metastasis A free excision results in complete cure in the vast majority of cases It is in this type of cases, especially those situated about the nose and eyes, that the use of caustics, while often successful, will occasionally render the growth inoperable The location must therefore be taken into consideration in selection of the method of treatment

The tumor cells may be cuboidal, cylindrical or spindle shaped They are characterized by a small amount of cytoplasm and by the fibrils which they produce At times they occur in a densely packed arrangement and, when of spindle shape, resemble a sarcoma quite closely

Occasionally a glandular carcinoma is seen about the face Only one of the type occurred in this series—a mucous gland, adenocarcinoma—arising in the floor of the mouth and extending over to the tongue and involving it

The connective tissue lesions occurring on the alveolar border form an interesting group of tumors usually referred to as epulides The soft or giant cell variety is the one type about which wages the controversy as to malignancy

The misunderstanding which has existed in the past concerning the exact nature of the giant cells found in neoplasms has contributed to this confusion The separation by Mallory[3] of true tumor giant cells from those of the foreign body type found in tumors has cleared the field in regard to the giant cell epulis In the majority of instances, the giant cells are all of the foreign body variety Again, these tumors may be confused with a malignant type of tumor of endothelial origin which exhibits intravascular giant cells and has been reported by Whitman[4] and Ivy [5]

---

[1] Bloodgood Carcinoma of the Lower Lip Surg Gynec and Obst 1914 18 404

[2] Slye Inheritability of Cancer in Mice Jour Med Research March 1915 p 193

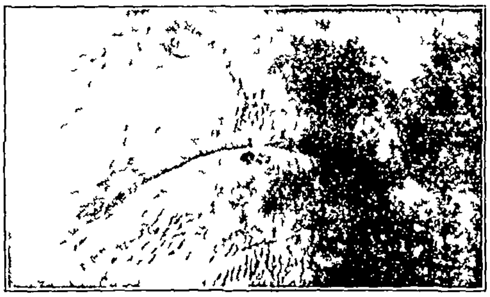

Fig 5—An early epidermoid carcinoma of the lower lip Patient is a plumber who has the habit of holding nails, etc in the mouth

Since these tumors represent forms of lawless growth of connective tissue cells, the important thing is to find out just what these cells are doing The rate of the growth should be ascertained by a histologic study of them, searching for mitotic figures, and determining the degree of differentiation to which they are attaining It should be noted whether these cells are arranging themselves in a position normal to connective tissue, or whether they are atypical in form and arrangement In a word, they should receive the same study as do connective tissue tumors elsewhere, and the diagnosis and prognosis be made accordingly

The prognosis of giant cell epulis, in general, is good, provided careful excision has been made The treatment should consist in a complete removal of the tumor and its point of origin

Several other varieties of the nonepithelial malignant neoplasms occur in connection with the face and mouth Sarcoma is a common tumor of the jaw This tumor may arise from the bone or connective tissue of the region The symptomatology is largely determined by the location and the rate of growth Although they are rapidly growing tumors there is but little pain until they become ulcerated or involve nerve trunks These growths should be excised well beyond the line of visible infiltration If metastasis has already occurred, since it usually takes place by way of the blood stream, the case is hopeless If in the frankly malignant case the growth is still a local process, complete excision will result in a cure

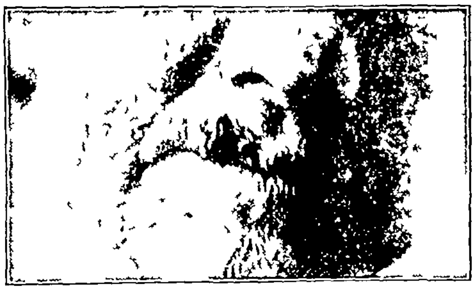

Fig 6—A hair matrix carcinoma of the lip

As the majority of cancers about the face and mouth are malignant epithelial tumors, metastasis to the lymph nodes of the neck occurs rather readily These metastatic groups of cells, however, may remain inactive for a long time and then take on an increased growth rate Only a small percentage of the late cases of cancer give rise to metastasis in distant parts Radical operation therefore, even in cases which present extensive involvement, gives a surprisingly high percentage of cure

Cancer of the face and mouth is comparatively easy of diagnosis and accessible for surgical treatment With this in mind, 3,007 deaths from cancer of the buccal cavity in the United States in 1913 is appalling

It is our desire to emphasize the need for close cooperation between surgeon and pathologist, and that here as elsewhere in dealing with new growths, the important thing, both in treatment and in diagnosis, is a thorough knowledge of the behavior of the tumor cells in the particular case under consideration

The end-results of surgical treatment of malignant tumors of the face and mouth compare favorably with those effected by medical science in the treatment of other disease (not considering, of course, the specific treatment such as antitoxin for diphtheria, etc), somewhere between 60 and 80 per cent of cures The earlier the cases are seen the higher the percentage of cures

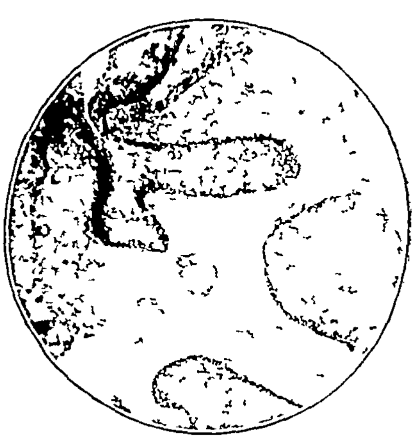

Fig 7—An adenocarcinoma of the floor of the mouth which promptly invaded the tongue

The operative technic in this region has reached a high state of perfection If further headway is to be gained against cancer of the face and mouth, it must be by the education of the public It is the duty of those who see so many cases after it is too late to educate the dentist, physician and the general public concerning these conditions which so often terminate in cancer, and urge the prompt radical treatment of cancer while it is still a local process The responsibility, therefore, rests with the stomatologist, the oral surgeon and the pathologist [6]

ABSTRACT OF DISCUSSION

DR FREDERICK B NOYES, Chicago There was one remark made in regard to the origin of the giant cells about which I know we have had some rather interesting evidence in the last year in the Research Laboratory of the University of

Illinois The character of the giant cells in the tumors about the mouth is characteristic of origin by fusion of other cells in the region

Dr H A Potts, Chicago The most important thing to be learned from the paper is the great importance of recognizing the possibility of these precancerous lesions The chief thing is to avoid irritation Any wound or abrasion on the mucous membrane of the mouth, lips or face, which does not heal or show a tendency to heal within ten days or two weeks should be looked on as very suspicious, and should not be treated expectantly We have all seen these cases The secret of success in their removal is early and extensive operation to take in all of the growth and metastases as well The chief point is that we must impress on the general practitioner of medicine and dentistry that these very serious abrasions should be looked after immediately and not given any palliative treatment that extends over a period of two or three weeks

Dr F B Moorehead, Chicago In the past there has been an error in the classification of tumors of the mouth, particularly of the mesothelial type A clear distinction should be made between the various forms of benign fibroma, the various forms of sarcoma and the giant cell tumors found in the mouth, which must not be looked on as highly dangerous We may have on the one hand, a giant cell tumor the result of cell fusion, and, on the other hand, a true giant cell sarcoma The giant celled tumor produced by cell fusion is a distinct pathologic entity, and is peculiar to the mouth It is not the same either clinically or histologically as the giant celled sarcoma We have begun the study of these peculiar giant celled tumors in the University of Illinois and hope to have something to say about them at a later date The term "epulis" should be discarded

ANKYLOSING OPERATIONS ON THE SPINE

A STUDY OF TWO SPECIMENS IN THE LABORATORY *

LEONARD W ELY, MD
SAN FRANCISCO

The two specimens described here were removed at necropsy

Case 1 (E 113) —The patient was a child of about 5 years, operated on for spinal tuberculosis by Dr Watkins, with Dr Ely assisting, five months before death The cause of death was pulmonary embolism The operation was a typical Hibbs

The specimen includes six vertebrae, the two lowest thoracic and four lumbar, one of which (the first lumbar) is badly diseased No motion can be detected in the operated portion between the spines, but the bodies move a little on each other

Sagittal Section—The diseased vertebra is crushed into a trapezoid, and its substance is decidedly harder and denser than is that of the other vertebrae, in spite of the fact that anteroposteriorly runs a band of necrotic tissue, so that the two halves (upper and lower) move on each other This rift in the bone communicates posteriorly with a collection of cheesy material which has pushed the posterior common ligament backward into the spinal canal The marrow of the affected vertebra appears yellower than that of the others

The impression one gets in examining the specimen is that too much of the work in the operation has been done above the diseased vertebra and too little below it The laminae of the three lowest thoracic vertebrae and of the first two lumbar are united by bone making of all five a firm bony mass Of the spinous processes themselves there is no trace. The union is interlaminar, not interspinous

Examination of the stained slide, which includes the diseased vertebra and those next above and below it, reveals that the diseased vertebra is in the form of a blunt wedge with the apex forward Its middle portion is worst involved, the diseased area divides the vertebra into an upper and lower portion and the products of inflammation bulge out posteriorly so as to narrow somewhat the lumen of the spinal canal The structure of the diseased vertebra is different from that of the vertebrae above and below It is more transparent, and the contrast between its trabeculae and its marrow is sharper

Histology—The upper and lower vertebrae are normal The marrow in each is lymphoid

The middle vertebra is badly diseased throughout most of its extent A small strip of approximately normal lymphoid marrow runs along the lower margin of the vertebra close to the fibrocartilage The rest of the marrow is badly diseased Much of it is fibrous marrow, very vascular, much of it is tuberculous Necrosis of the tuberculous areas is well advanced Many of the trabeculae are dead, and areas of calcification form a prominent feature The whole middle portion of the vertebra has broken down, and is represented by a transverse band of necrotic material in which are many areas of calcification The trabeculae here show well marked rarefying osteitis and are practically all dead The tuberculous granulations have burst through, have consumed the thin cortex of bone posteriorly, and have formed an abscess beneath the posterior ligament The abscess contains cheesy granulations, with many areas of calcification, many dead bone trabeculae, and one small sequestrum just discernible by the naked eye Communicating with the diseased mass, and anterior to the disk between the diseased vertebra and that above it, is another somewhat smaller abscess cavity containing tuberculous granulations, and much necrotic and calcified material It looks as if it had been formed by the squeezing out of material by pressure on the diseased vertebra The lamina of the diseased vertebra is united to that of the one above it by bone, and this is separated from the next one above it by a very narrow interval of fibrous tissue in which bone is forming The lamina of the diseased vertebra is separated from that of the one below it by fibrous tissue, in which no bone formation is taking place (Evidently at the line of section the band of bony union mentioned above has not been included)

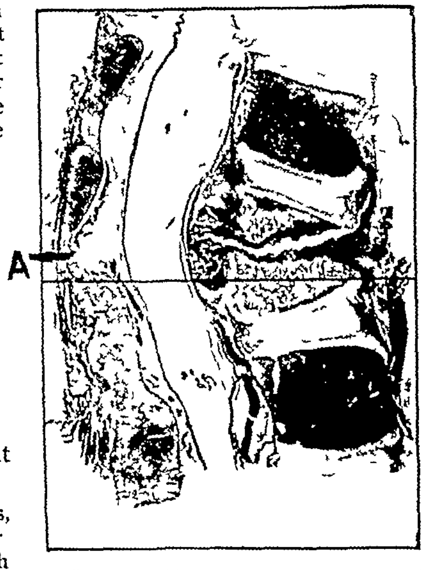

Fig 1 —Hibbs operation Photograph of stained slide showing diseased vertebra between two sound ones Bony union at *A* Natural size

We have then, as the result of the operation, bony union in the operated area, and a tuberculous process still active in the body of the vertebra

This specimen, besides its relation to an ankylosing operation, throws light on a point which has been up for discussion before this section for the past two years You will remember that Mr Fraser maintained that tuberculosis started in the synovial membrane, and that circulating toxins caused the marrow in the adjacent bone to change from lymphoid to fatty or myxomatous marrow, not until then could the disease gain a foothold in the bone From which joint could the extensive involvement of this vertebra proceed? How is it possible that one vertebra could be so badly diseased, while the vertebra on the other side of the offending articulation escapes entirely? Mr Fraser, I believe, has confused cause and effect The fatty and "fibromyxomatous" marrow is not the precursor of marrow invasion, but the sequel If not the only determining factor in the location of tuberculosis in the bone, at least by far the most important one is the presence of lymphoid marrow No lymphoid marrow, no tuberculosis

* Read before the Section on Orthopedic Surgery at the Sixty Seventh Annual Session of the American Medical Association Detroit June, 1916

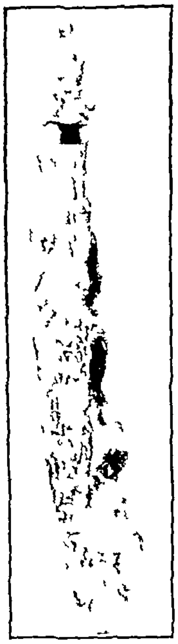

Fig 2 —Albee operation Posterior aspect of specimen showing graft in place

Case 2 (E 127) —Lumbar spine on which an Albee operation had been performed two years previously by Dr McChesney Apparently firm union had taken place A spondylolisthesis was present, accounting for the paralysis of the lower extremities A large cheesy mass was present in the body of the fourth lumbar vertebra, well walled off

Three and a half years previous to death the left hip had been resected for tuberculosis, and about one and a half years later an Albee operation had been done on the spine by Dr McChesney At about the same time the internal genitals had been removed The patient had been admitted to the hospital in coma and died two days after admission Paralysis of the lower extremities was said to have been present for some time

Anatomic Diagnosis at Necropsy (Dr Ophuls) —Tuberculosis of intestinal tract, primary tuberculosis of lymph glands, mesenteric, healed Tuberculosis of spine, lumbar region Operation Albee Tuberculosis of hip (healed) Bronchopneumonia Cirrhosis of liver Adiposity general Liver, fatty Heart fatty Gastritis, chronic

The specimen consists of the spines of the lumbar vertebrae, the last four firmly joined by a thick bridge of bone, the graft The graft is firmly united to each spine, so that its exact limits cannot be distinguished, only a ridge where it joins the spines — an irregularity The soft tissues were firmly attached to the graft as well as to the spines, and their dissection was quite difficult Dr McChesney is strongly of the opinion that the graft has grown in thickness since the insertion Anteroposterior section of graft, and the embedding portion of the spine of first lumbar vertebra were made for study

Section of a piece of the body of the fourth lumbar vertebra, including the wall of the abscess, includes bone and intervertebral disk The bone trabeculae stain very poorly Their margins take the eosin stain well, but not the rest of them The bone marrow is lymphoid and fatty None of it is tuberculous The wall of the abscess is evident—a small fringe of necrotic material, well encapsulated by fibrous tissue The process is in the stage of healing

Histology—The graft appears as a cap of dense bone on the end of the spongy bone of the spinous process The cortical bone of the latter, as well as its trabeculae, are directly continuous with the bony tissue of the former The spinous process shows normal spongy bone with lymphoid marrow, and a rather thin cortex on the sides

The graft at its surface, that is, directly under the periosteum, presents a layer of what is presumably new bone, staining deeply with hematoxylin Its cells can be seen in their lacunae and stain well Here and there blood vessels penetrate this superficial layer, and small blood vessels are present through the graft

Immediately under the superficial layer is a stratum, some of which seems living and some dead In a general way the live bone is immediately adjacent to the haversian canals, and the dead bone fills in the spaces among the haversian systems, but this rule is only a general one The rest of the graft consists of dense bone, whose cells stain fairly well for the most part, though they do not fill the lacunae The marrow is normal fatty No rarefying osteitis is present

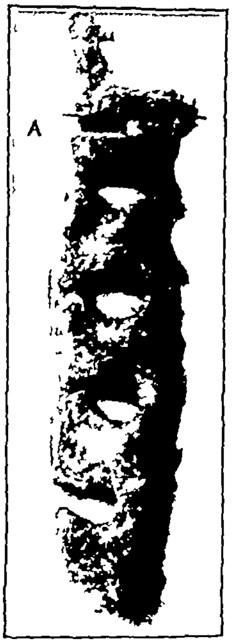

Fig 3 —Albee operation Lateral aspect of specimen the graft on the left with a specimen removed at *A* for study

We have here, then, a firmly united graft after two years, composed of fairly normal bone with fatty marrow, containing blood vessels At the surface is apparently new bone The disease in the body of the vertebra is in the stage of healing

Apparently it is impossible to tell with certainty dead from living bone under the microscope In certain of the slides most of the cells are missing from the lacunae, and the bone might be pronounced dead, but if it were dead it would hardly resist absorption for two years, blood vessels probably would not be seen in its meshes, nor would ordinary fatty marrow be seen in it

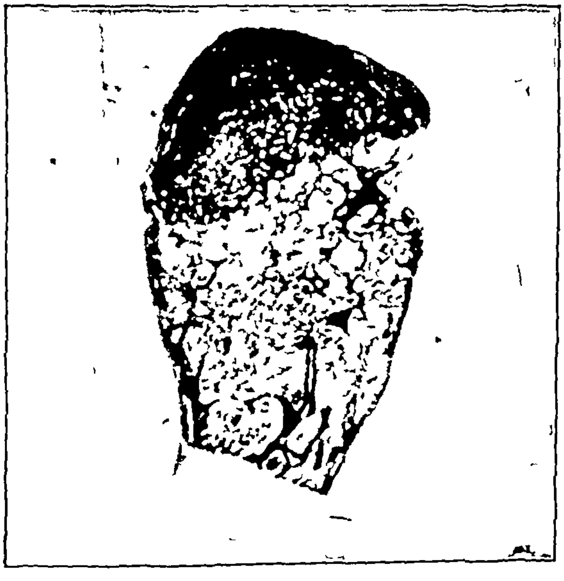

Fig 4 —Albee operation Bone graft in place *The graft appears as a cap of dense bone on the spongy bone of the spinous process* Photograph of the stained slide enlarged four diameters

Besides these two specimens, I have been fortunate in seeing one other secondary operation, and of doing one myself The former was done on account of the persistence of pain and discomfort, and of increase of deformity, following a Hibbs operation The laminae in the area of disease were found fused for the most part, but a joint still persisted in one or two places in the operated area A graft was removed from the tibia and was sewn tightly against the denuded laminae The result is described as satisfactory

The second case was also one in which a Hibbs operation had been attempted, and in which pain persisted and deformity increased The spines were absent, and no indication of union was present among the laminae The vertebrae could be seen to move freely on one another during respiration The treatment was by tibial grafts sewn tightly to the denuded laminae The result ten months later was excellent All symptoms of active disease had ceased, bony union apparently had taken place and the marked kyphosis present previously seemed, by tracings, to have lessened

One other fact needs mention In a rather small experience in spinal ankylosing operations, I have lost two patients on the table In neither was a necropsy done A colleague has recently told me of another fatality

Personally, I am strongly in favor of these operations in spinal tuberculosis, and regard them as curative in a formerly incurable disease, but their dangers should not be minimized I regard my two fatalities as due to the anesthetic, and since the occurrence of the second one have never done the operation without a skilled anesthetist

Lane Hospital

ABSTRACT OF DISCUSSION

Dr Russell A Hibbs New York There is no question that we can get ankylosis of the spine by operative procedure and I have no hesitation in saying that the earlier it is done, the better for the patient Some have said that the patients to be operated on are those who are not doing well Those who have had experience with Pott's disease know that it is very difficult to decide which patients are doing well over a long period, and which are not, and I do not believe that these operations are serious I therefore think it is better to operate, and my associates have done 350 operations without any operative mortality We have always had a good anesthetist, and, as Dr Ely says this is very important Regarding the details of the operation The success of the procedure depends primarily on the dissection What we wish to accomplish is fusion of the bone and not splinting of the vertebrae We must eliminate motion We must, therefore, eliminate the articulation, and hence, we must fuse the bones that participate in the formation of the articulation In the spine we have a large area of perfectly healthy bone to operate on The posterior aspects of the vertebrae are, as a rule, healthy, and may be fused with certainty if a thorough dissection is made at operation

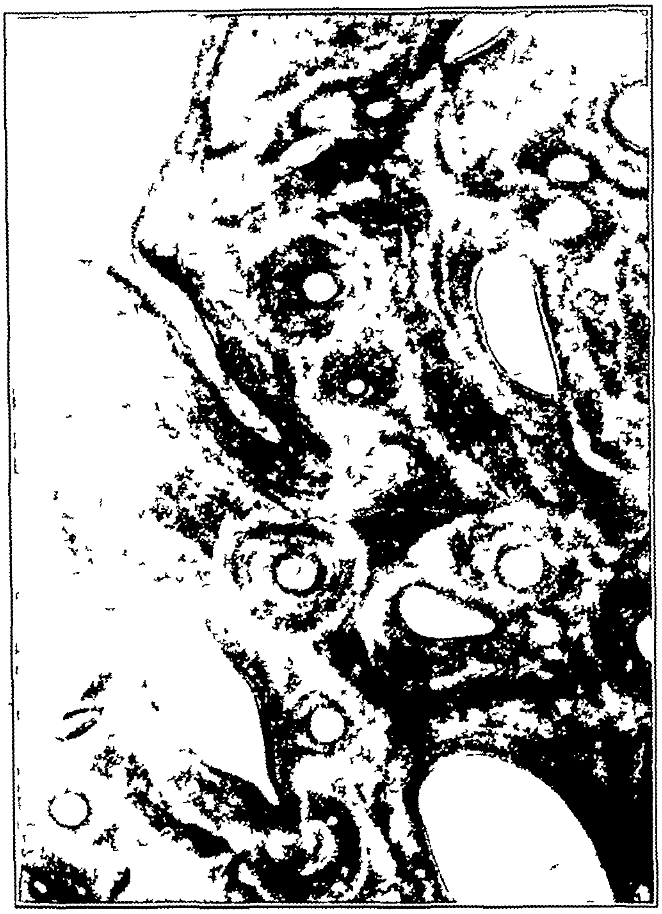

Fig 5 —Albee operation Photomicrograph of portion of graft showing many empty lacunae, and a blood vessel entering the bone Note difference in staining of bone.

Dr Reginald H Sayre New York I have some cases under observation at the present time that show that a bone splint does not under all conditions remain, but sometimes becomes absorbed I have three patients two adults and one child in whom tibial splints were placed by others In the small boy I have had roentgenograms made each month and have been very much interested to note the gradual disappearance of this bone splint. At first the child was purposely left without protection, but later, after six months of watchful watching, he was placed on a board After about a year or so, he got a perfectly good spine, but no sooner than would have been the case without operation The two adults who had been operated on before coming under my observation were unable to walk, except by supporting themselves by placing their hands on their knees, and Roentgen ray examination showed no trace of a bone splint I have no doubt that a bone splint had been put there at some time in the past, because the scars looked as if that had been done, and because the operations were done by gentlemen of experience I have no doubt, also, that it was a well done operation in each case but, for some reason, the bone did not form a bridge as in the specimen passed around by Dr Ely The bone had disappeared, and there was recurrence of the symptoms for which, I presume, the operation was done

Dr James T Watkins San Francisco We have done between fifty and sixty of these operations at the Children's Hospital, approximately an equal number of Hibbs and Albee operations The patients seem to get well with about an equal degree of assurance following either operation I think that on the whole I prefer the Hibbs operation Certainly the Albee is quicker to do Dr Hibbs says that in the specimen being passed around I did not fuse my articular processes However, that is easily explained This refinement of the operation did not appear in Dr Hibbs' earlier publications and I had not heard of it at the time I did this operation Still my earlier patients got well without it This child, you know died of lung condition six months after operation In this specimen most exact fusion between the adjacent spinous processes and between the adjacent laminae has taken place There is no evidence of bony absorption I cannot explain this apparent discrepancy I have had occasion once to operate again on a patient who had been operated on a year previously by the Hibbs method and I have seen the specimen which Dr Sherman removed in another Hibbs case in the course of a laminectomy Macroscopically the spines had been transmuted into a broad, flat, thin plate of bone more nearly resembling a sternum than anything else

Dr Edwin W Ryerson, Chicago It is undoubtedly true that we can obtain bony fusion of the vertebrae by either of these methods The choice of the operation is not on a very well defined basis My own impression is that if I think the patient needs a rapid operation I can do the Albee operation a good deal faster than I can properly do the Hibbs operation The first few of the latter operations that I did were done before I saw Dr Hibbs do this operation, and after I had seen his careful way of doing it I knew why my first two patients did not have as good a result as I thought they should have had I find that in younger children we must protect the spine for a longer time than I at first believed necessary

I have seen, now, a good many of the late results of both the Hibbs and the Albee operations that I have performed A number of the younger children on whom I did either kind have not been protected long enough, with the result that an increase in kyphosis has taken place We should protect such patients for a long time afterward In regard to what Dr Sayre says of the disappearance of the Albee grafts in some of the younger patients, it is not always easy to see in the roentgenogram the shadow of the graft I have cut down in one case in which the roentgenogram did not show the bone, only to find that there was bony ankylosis It was slightly flexible, and the reason the boy was reoperated on was that at the top of the splinted area 3 inches above the diseased area a new focus of tuberculosis had appeared I put in a new graft, going many vertebrae higher The splint in the Albee operation is flexible, in children, and the patient should have protection until it is no longer so How long this may be, I do not know The most striking case that I have had is that of a girl on whom I operated in 1912 A large psoas abscess which she had at the operation has disappeared, and there are no symptoms whatever You can feel a massive bone formation in the spine, from the splint, and the deformity is thought to be less than it was a few months after the operation She had careful conservative treatment by braces for a year before operation, but the condition grew worse She is now completely cured, four years after the operation

Dr J T Rugh Philadelphia One thing about this operation that has impressed me the most strongly is the very low mortality In a series of eighty cases, I have lost but one patient In that case, when I was through, the anesthetist could tell me every step of the operation The patient had died on account of the ether

Dr R A Hibbs, New York We should give these children and adults very careful protective treatment after operation It is a great mistake to assume that you are eliminating the disease so quickly We treat the patients just as if they had not been operated on so far as protection is concerned Children are treated for a year or eighteen months and adults, six months to a year There have been many children whose parents have been disappointed because they were operated on and let go, without proper after-care I want to protest very strongly against that

Dr Leonard W Ely, San Francisco I must differ with Dr Watkins' contention The section is taken approximately directly through the middle, where the base of the spinous process would be, and here there is little, if any, bony union At the side one sees in the gross specimen the union of the laminae When you cut off the spinous process and turn it down, probably that spinous process is doomed Without bringing up this subject of the ultimate fate of a bone that is grafted, I would say that that spinous process may be likened to a man who is dead from some accident, but who, with artificial means of respiration is brought back to life That life cannot be supplied to the spinous process except by contact with another bone or connection with another bone by periosteum What Dr Watkins says about the difficulty of the Hibbs operation I should be inclined to stand by and accentuate Whenever I get an opportunity, I go to see the originator of the operation operate The beauty of the dissection and the carefulness with which Dr Hibbs does the operation seem to be the determining factors in the results obtained

BLASTOMYCOSIS OF THE TONGUE *

GORDON B NEW, M D
ROCHESTER, MINN

Blastomycosis is usually considered a skin lesion or a systemic disease In a review of the literature I have been able to find only one case of blastomycosis of the tongue Copelli[1] in 1913 reported a case of a woman who presented a tumor of the tongue consisting of an aggregation of six rounded nodules on the back part, with some enlargement of the submaxillary glands She presented also blastomycetic lesions on both feet Examination revealed the blastomyces in the affected tissues The treatment used and the end-results are not stated in this case I wish to report a case of blastomycosis of the tongue examined in the Mayo Clinic

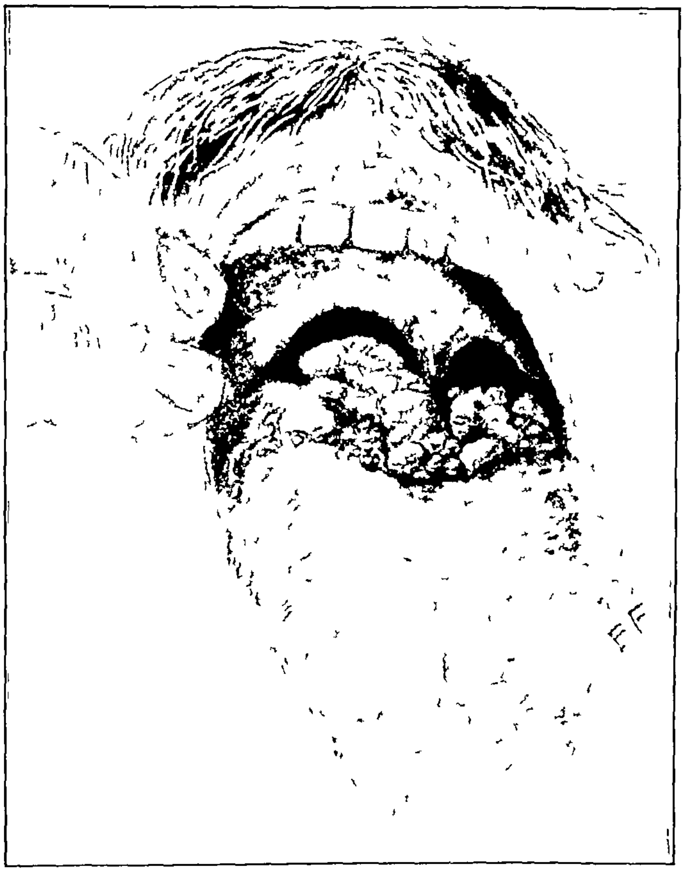

Fig 1 —Blastomycetic tumor of the tongue

J S M man, aged 52 chief of fire department, came to the clinic, Feb 7, 1916 for tumor of the tongue which had been first noticed eleven months previously The family history was not important Thirty-two years previously he had had a chancre which, from the history, was questionably specific He had no secondary lesions He smoked and chewed moderately, but had not used alcohol for thirty-one years Sixteen months before examination at the clinic he had had tonsillitis and was treated by a physician Eleven months before he had received an electric shock from touching an electric fixture with his right hand On the following morning he noticed that his tongue was larger than usual The next day he consulted a physician, who found a tumor at the base of the tongue and removed specimens for diagnosis These specimens were reported as being "mostly lymphatic gland containing much granulation tissue, no evidence of malignancy or tuberculosis" Electric treatments for the tongue were given at this time Nine months before coming to the clinic, he was given five treatments with neosalvarsan and eleven injections of sodium cacodylate with no resulting change in the tumor At this time he had much difficulty in swallowing and talking A month later he consulted a physician who diagnosed the condition as lymphadenoma and cauterized the tumor several times with an electric needle

---

* From the Mayo Clinic

[1] Copelli M Jour Cutan Dis, 1913 **31,** 51

This was done once a week over a period of two months There had been shortness of breath for eight months, and also great difficulty in swallowing solids, though fluids were swallowed readily The tumor seemed to be increasing in size but no swellings in the neck were noted The patient had lost 60 pounds since the onset of the trouble, and found it almost impossible to sleep at night as the tongue fell back and obstructed the pharynx, causing dyspnea The normal weight had been 220 pounds, weight at the time of examination, 150 pounds Speech was difficult, the voice was thick and mostly nasal in character

Examination of the mouth showed a nodular tumor at the base of the tongue filling the entire pharynx so that the postpharyngeal wall was not visible It was impossible to press down the tongue in order to examine the posterior part of the growth The tumor was quite firm, but did not have the hardness of malignancy It appeared in rounded folds between which were grayish-white areas There were no lesions in other parts of the mouth The systolic blood pressure was 110, diastolic blood pressure 70, pulse 96, temperature 98 6, urine negative The white blood count was 5,400, red blood count 5 270,000 Roentgenoscopy of the chest was negative, as was also the Wassermann test No lesions were found in any other parts of the body The tissue removed from the tumor showed microscopically lymphoid hyperplasia with great numbers of plasma cells Blastomycetes were found on culture from the areas in the folds of the tumor A culture of blastomycetes injected into guinea-pigs yielded negative results

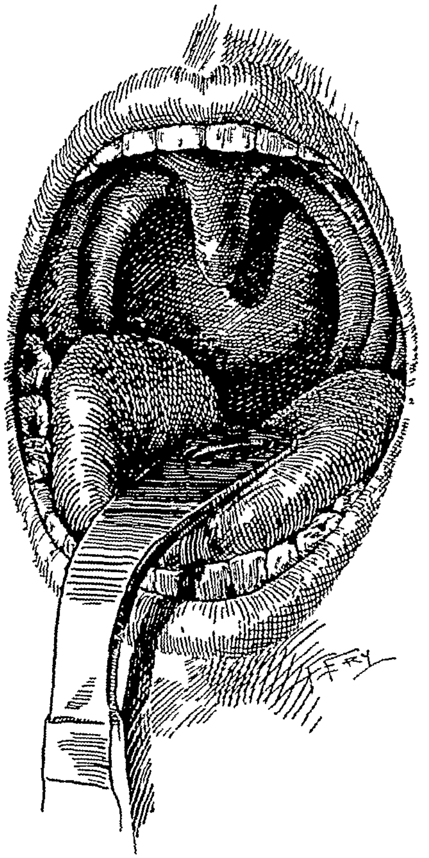

Fig 2—Same as Figure 1 after condition had cleared up

A diagnosis of blastomycosis was made on the presence of blastomycetes with secondary lymphoid hyperplasia of the tissue of the tongue, and because all other findings were negative Malignancy, tuberculosis and syphilis can be readily ruled out from the data stated in the history and the appearance of the tumor The patient was given potassium iodid 10 drops three times a day the dose being increased by 2 drops daily until 125 drops were taken three times daily Iodin was used locally to swab the tumor once a day, and radium, twenty-six hours of a 22 mg tube, was given for a period of three weeks Five weeks after this treatment the patient returned showing marked improvement in his general health He was then able to eat and swallow without difficulty, had no dyspnea on exertion, and had gained 20 pounds in weight. The tongue showed remarkable improvement, and in a direct examination of the mouth very little of the tumor was visible It was possible to see the pharynx, and by the use of the laryngeal mirror it was found that the tumor extended down the base of the tongue to the epiglottis

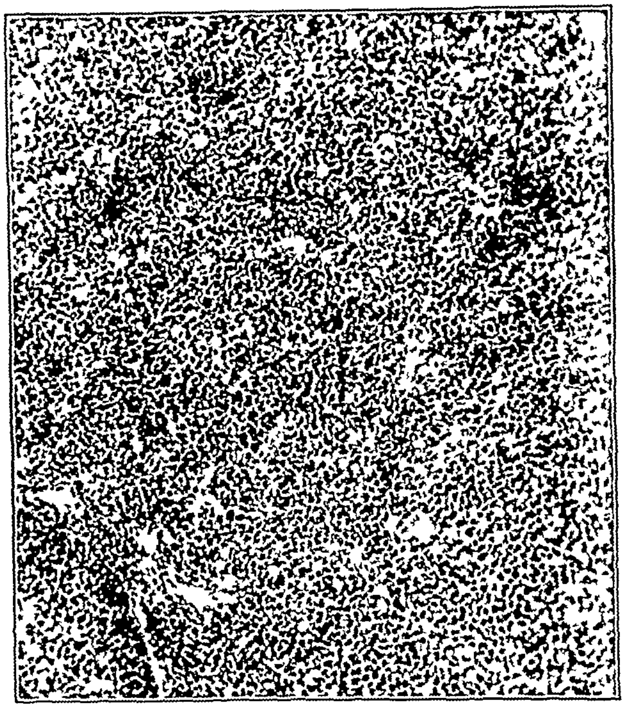

Fig 3—Low power lymphoid hyperplasia

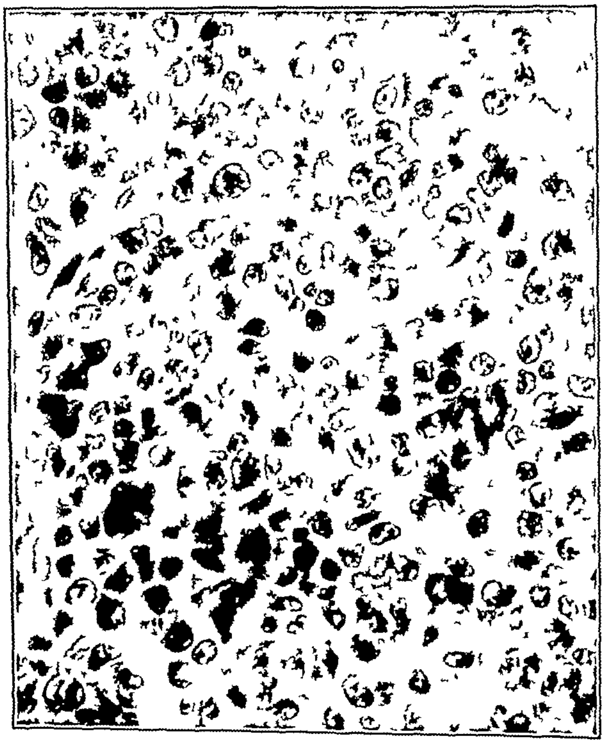

Fig 4—High power great numbers of plasma cells and lymphocytes

Sixteen hours of a 50 mg tube of radium were then given for a period of two weeks, the iodin again applied locally, and the potassium iodid continued Four weeks later the patient returned feeling perfectly well, eating and sleeping without any trouble He had gained 15 pounds since his last visit The tongue appeared normal on direct view, and it was possible to see the pharynx readily By the use of a laryngeal mirror a nodular tumor 1½ inches in diameter was seen down at the base of the tongue About it were several small nodular tumors The larger one was removed by a snare and forceps On microscopic examination it showed pure lymphoid hyperplasia The smaller nodules were treated with radium, sixteen hours of a 22 mg tube Iodin was applied locally and the potassium iodid continued When examined, Aug 10, 1916 the tongue was normal The patient had gained 16 pounds since his last visit, and was feeling well

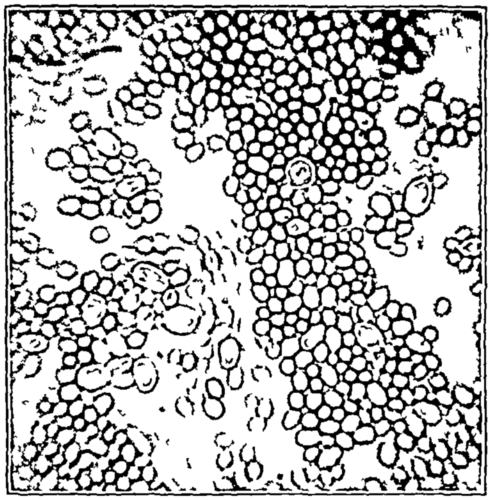

Fig 5 —Pure culture blastomycetes

This case is of interest because of the rarity of blastomycetic lesion of the tongue and the remarkable results of the treatment The nodular appearance of the tumor seemed to be the same as that reported by Copelli[1] It must be remembered, however, that blastomycetes may be found in the tonsils and lingual tonsil so that the presence of blastomycetes alone does not necessarily mean that the disease is true blastomycosis It would seem the lymphoid hyperplasia was a secondary condition stimulated to growth by the presence of blastomycetes, possibly in the lingual tonsil

---

Malaria in the United States—As a result of the study of malaria in the United States during the past four years, J W Trask of the Public Health Service (*Public Health Report,* Dec 22, 1916) sums up the situation as follows In the territory extending from the Gulf of Mexico to a line north of the Ohio River, and from the Atlantic seaboard to and into the eastern part of Kansas, Oklahoma and Texas, few, if any, localities are entirely free from malaria In most of the lowlands it is very prevalent, in the mountains and better drained areas, less prevalent The disease is also endemic in southeastern New York and parts of Connecticut, Rhode Island and Massachusetts, and in California in the Sacramento and San Joaquin valleys There is probably no state in the Union in which the disease is not present and in which *it is not spread* by mosquitoes grown locally The disease constitutes one of the big national health problems It is also an economic problem of importance The actual geographic distribution of the disease and its relative prevalence can be definitely determined only by making painstaking malarial surveys or by requiring cases to be reported to the health authorities and the authenticity of the reports verified by blood examinations

---

A NEW OPERATIVE PROCEDURE FACILITATING THE ADAPTATION OF ARTIFICIAL DENTURES *

H A POTTS, MD
Fellow of the American College of Surgeons
CHICAGO

Authorities on prosthetic dentistry agree that, before taking an impression, a careful and comprehensive study of the mouth from both the physiologic and the pathologic aspects should be made In an edentulous mouth, the thickness and firmness of the soft tissues are noted, as well as stomatitis, leukoplakia and other diseased conditions, if they are present The bony ridges are studied with regard to undue pressure which may be brought to bear on them

If natural teeth are to be retained, they and their supporting structures must be restored to health, and in either case the attachments of muscles are noted All of these conditions are studied in order that the denture may meet the following requirements, namely, that they may be useful, look well and be comfortable (Prothero) Primarily all of these depend on their retention which is made possible by two physical factors, adhesion, which plays the lesser role, and atmospheric pressure

On account of the varying density and compressibility of the different tissues in the same mouth, both impression and model are scraped in order that a perfect adaptation of the plate to the tissues may be maintained under all the various movements and different degrees of stress to which the plate may be subjected

While the foregoing applies to the normal mouth, the same adaptation, adhesion and atmospheric pressure apply to the abnormal mouth To correct the abnormal mouth, surgical procedures are resorted to, namely, the removal of loose fibrous or spongy tissues, the cutting of fibrous bands, the excision of spicules of process, or well defined osteoid growths which occur in the palate, labial, lingual or buccal regions of the jaws

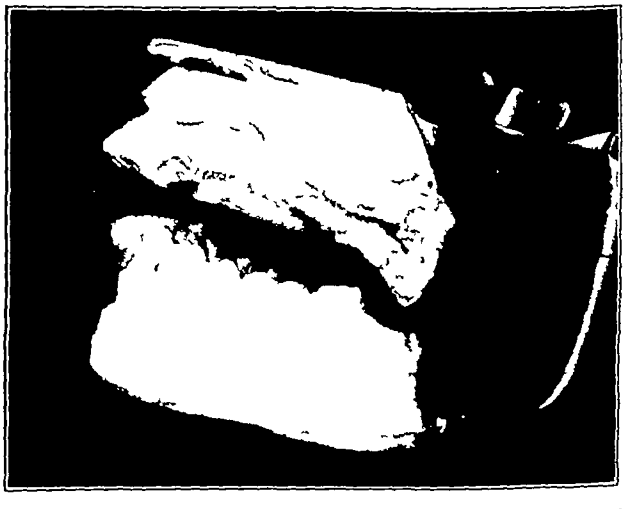

Fig 1 —Casts of upper and lower jaws showing their abnormal relation to each other and marked protrusion of the upper bony arch

---

* Read before the Section on Stomatology at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

The removal of exposed, projecting process after extraction should be more frequently done than is our habit

There is another quite common condition which can be remedied by surgical interference and which, so far as I can judge from a review of the literature and conversation with some of the leaders in dental thought, has not been pointed out, and that is the practical elimination of bony undercuts in the upper jaw If this is done, the making of metal dies and the swaging of metal plates would be simplified, and the making of cores unnecessary

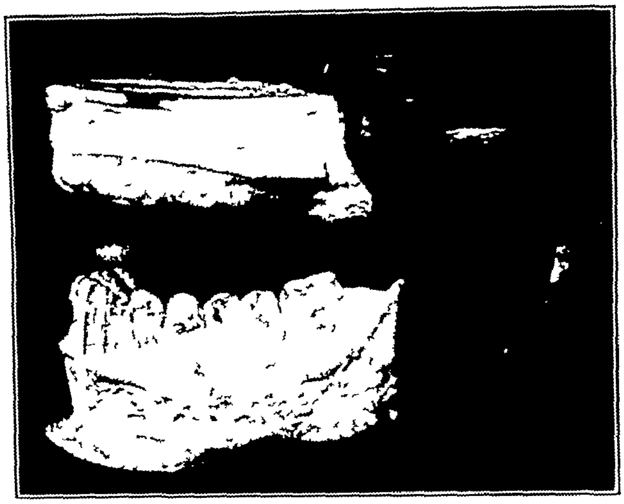

Fig 2 —Casts of upper and lower jaws after operation, showing normal relationship

A conformation which requires the slipping in of a plate as a shoe does not favor retention, but rather militates against it, as the chief factor in retention is atmospheric pressure

When such a plate, the labial and buccal borders of which are forced into undercuts at one or more places, is subjected to the forces of mastication, the upper borders are carried away from the soft tissues, and air passes beneath the plate with its consequent release

The study of the case here reported and the excellent result obtained by surgical means on the bony process seems to justify its more frequent performance

The patient, a woman, aged 50, had long since lost all upper teeth posterior to the cuspids, and mastication on the remaining six anterior ones, together with some destruction of peridental membrane, had resulted in a marked protusion Her dentist, Dr F H Stafford of Chicago, extracted the remaining teeth and proposed to make an upper denture, but found it quite impossible.

He referred her to me for surgical intervention As can be seen by the illustrations and models there is a very marked protrusion of the alveolar process which was covered with quite normal gum tissue and mucous membrane (Figs 1 and 3)

Two incisions along the alveolar ridge, extending from the second bicuspid region on the one side to the corresponding point on the other were made which being 'quarter moon' shaped, eliminated the gum tissue which was between the teeth and left two cleanly cut borders of the flaps A medium vertical incision extending from the reflection of the mucous membrane joined the other incision at right angles The resulting flaps, together with the periosteum were reflected

By means of rongeur forceps and large bud shaped burrs the outer plate of bone was removed from the first bicuspid socket on the one side to the corresponding one on the other side The thickness of bone removed varied, in the bicuspid region being the outer plate only, but the remainder extended to the posterior walls of the alveoli

The incision along the alveolar border as well as the vertical one was closed with interrupted horsehair sutures, there was primary union within ten days Impressions of the new normal mouth, as seen in Figures 2 and 3, were taken, and a perfectly satisfactory denture constructed

31 North State Street

ABSTRACT OF DISCUSSION

Dr Chalmers J Lyons, Ann Arbor, Mich This is the first operation of this kind that has been called to my attention, but I can see the good that can be accomplished in a great many of these seemingly impossible cases for the fitting of artificial dentures Dr Potts has practically restored this to a normal condition This procedure should be brought to the attention of men working in prosthetic dentistry, because there is no doubt that a great number of cases come before them in which such an operation would simplify the fitting of the artificial denture

Dr Eugene S Talbot, Chicago I have removed small pieces of the alveolar process for the same purpose, but never to the extent that Dr Potts has removed it In a number of cases I have also dissected up the buccinator muscle, which extended down to the border of the alveolar process, cutting it clear up to the zygomatic process, in some cases a very little, in others quite extensively, but I would like to know how to prevent the tissues from growing together again That has been the most difficult proposition I have met, especially in cutting the frenum of the lip, to keep the parts from coming together and healing over

Dr H A Potts, Chicago In regard to the inquiry of Dr Talbot, I think I can best answer that by referring to the operation for widening the pylorus of the stomach, known as the Heineke-Mikulicz operation, which involves making an incision in one direction and closing it in the other The same principle can be applied in the case of the frenum By carefully suturing the mucous membrane together it will make the reflection continuous, consequently there will be no raw surface to oppose the raw surface at the gum, and it cannot become attached because it is covered with mucous membrane The operation can be varied by suturing the mucous membrane into that area of the buccinator region I have since seen an enormous exostosis of the labial surfaces and the tuberosities which almost filled the palate Another interesting case has been reported of an exostosis that almost filled the palate In such a case I see no reason why an incision could not be made from one end to the other and the bone chiseled away if necessary, removing part of the palatal, mucous membrane and periosteum suturing that down and making a perfectly normal mouth As I have said, many of these things have been done, but really not with the idea of facilitating the fitting of an artificial denture, and I think by paying a little closer attention and observing these cases they can be benefited very materially

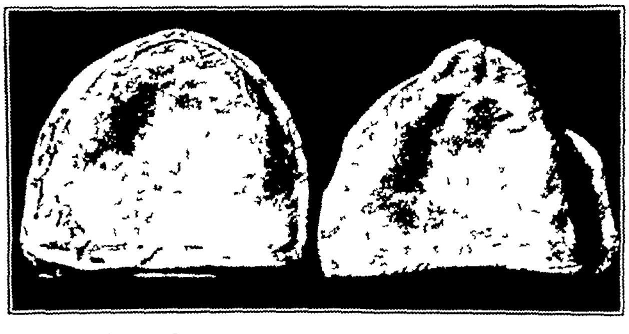

Fig 3 —Casts of upper jaw made from impressions taken before and after operation the result is a perfect arch

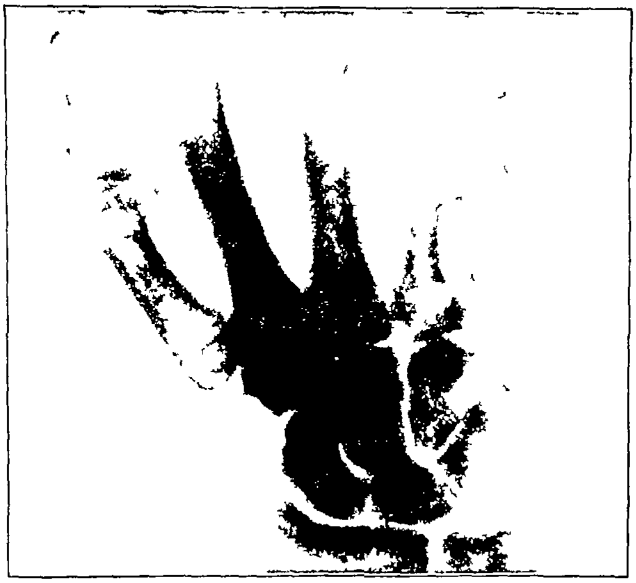
COMPLETE FORWARD LUXATION OF CARPOMETACARPAL ARTICULATION OF THUMB

REPORT OF A CASE

E L BERRY
CHICAGO

The articulations between the carpus and the metacarpal bones are so constructed as to make complete luxations of these joints somewhat rare From a surgical point of view these articulations are divided into two parts first, the articulation of the multangulum majus (older terminology, trapezium) with the first metacarpal, second, the articulation between the inner four metacarpals and the carpus The latter acts functionally as one continuous joint, having a synovial membrane in common This union is of the arthroidal type, while the carpometacarpal joint of the thumb is one of reciprocal reception and is capable of motion in all direction, except axial rotation This joint is separate from the other set, is surrounded by a strong separate capsule, and has its own synovial membrane Although dislocations at this point are more common than at the other carpometacarpal joints, of the cases reported very few have been forward, backward luxation being by far the most common



Displacement of os multangulum majus

REPORT OF CASE

H, man aged 30 baggage man at railway station came to the office three hours after the injury which occurred as a trunk which he was loading fell to the ground The wrist was twisted causing the dislocation There was severe pain and the patient had difficulty in using the hand, especially the thumb

When I first saw the patient there was some swelling at the wrist and at the base of the thumb There was considerable pain Adduction of the thumb was difficult, painful and incomplete The greater multangular was easily palpable on the ventral aspect, behind which the proximal end of the metacarpal formed a hard prominence beneath the thenar eminence There was little or no shortening of the thumb The roentgenogram shows the greater multangular displaced anteriorly and medially, with a considerable space between the proximal end of the metacarpal and the neighboring structures There was no fracture as often occurs, of the proximal ends of the first or second metacarpals or of the greater multangular itself

Reduction was accomplished by the following procedure The patient's thumb was grasped firmly in the operator's right hand, the wrist in the left, in such a manner that the tips of both of the operator's thumbs rested on the displaced bone Then with traction on the thumb, and posterior and lateral pressure on the greater multangular, the wrist was slowly flexed As the bone assumed its normal position there was a decided give felt by the operator, and a snapping sound that was clearly audible The roentgenogram taken after the reduction showed the bone in its normal position Inspection and palpation revealed no differences as compared to the other wrist, save the swelling

A thin layer of bandage was placed round the wrist, over which was tightly wound a 3 inch strip of adhesive The patient was able to work two weeks later, although he still wore a wrist support and the joint was somewhat weak

1020 La Salle Street Station

EARLY DIAGNOSIS OF TABES DORSALIS*

WALTER F SCHALLER, M D
SAN FRANCISCO

Tabes dorsalis, as its name would imply, is a disease characterized by a degeneration of the posterior columns of the spinal cord Spiller,[1] however, as far back as 1897, defined tabes in reality as a cerebrospinal disease, and indeed, certain symptoms referable to the cranial nerves may so dominate the clinical picture that the cord symptoms may be insignificant or even pass unnoticed Prominent among these symptoms are those which are referable to the eye Primary optic atrophy is especially frequent

Recently, E Frey,[2] from Schaffer's clinic, has studied 286 cases of incipient tabes, classifying these as oculo-pupillary, dysuric, lancinating and mixed forms, and studying sixty of them also from the standpoint of prognosis

The session[3] of the Society of Neurology in Paris, Dec 30, 1911, was devoted to a discussion of the symptomatic limitation of this affection ("Delimitation du tabes"), and the prominence of the men who took part in this discussion makes it a worthy contribution to the recent literature of this subject J Nageotte maintained that tabes could be defined only by terms of pathologic anatomy and by the etiology, reiterating his radicular nerve theory Nageotte's conception was accepted by such clinicians as Babinski and Andre Thomas, the latter, however, not regarding the radicular lesion as pathognomonic The question of monosymptomatic tabes was raised, and although many of those taking part in the discussion held that an isolated symptom, characteristic of tabes in a patient with a history of syphilis and presenting a typical evolution, might make a diagnosis of tabes very probable, yet an absolute diagnosis was not justifiable (Erb[4] in a recent communication elsewhere also expresses a similar opinion) Henri Dufour reported a necropsy case in which the only symptom during life was an Argyll Robertson pupil and in which the cord showed the characteristic lesions of tabes

In answer to the question, how early one may venture to diagnose tabes, the quotation from John Babinski may not be out of order

> A patient presents the sign of the Argyll Robertson pupil, furthermore, he is subject to lancinating pains showing the characteristics of those which occur in a plain case of tabes and finally, notwithstanding the subjective pain, intensive faradization of the calf muscles is painless, in such a case, even in the absence of any other symptom, a diagnosis of tabes is almost sure I can almost say as much of a patient in whom all the reflexes, including the pupillary reflex, are normal, and who presents together with the sensibility disturbance just noted a characteristic lymphocytosis of the cerebrospinal fluid Certainly the diagnosis is not of a mathematical certainty, but of a great probability

This statement, coming from a clinician of the prominence of Babinski, is noteworthy, and demands attention and further analysis It is a long step from this picture to the picture presented by the classical tabetic difficulty in walking, Romberg, ataxia, absent patellar reflexes, fixed pupils, advanced sensory disturbances and often typical complications Syphilis is now regarded as the cause of tabes Even Erb,[4] who has always recognized the important part which syphilis has played in this affection, has withdrawn from his former reserved position, and now states that syphilis is the sole cause outside of very exceptional and doubtful cases How syphilis acts on the spinal cord has given rise to many theories, the toxic theory, and the meningeal theories of Obersteiner and Redlich, and of Nageotte occupying the foreground of attention A considerable support to the toxic theory has been given by the recent experiments of Spielmeyer[5]

In order to determine to what extent chronic leptomeningitis of the spinal cord exists in cases of tabes which have been examined at necropsy, I have collected fourteen cases, examined microscopically, from the records of the Pathological Department of Cooper Medical College and Stanford Medical School between the years 1898 and 1916 Thickening or cellular infiltration of the spinal meninges most marked in the posterior portion of the cord was present in all of these cases

Recently, Spiller,[6] in discussing the pathology of tabetic ocular palsy, has stated that in his experience the most characteristic lesion in cerebrospinal syphilis is round cell infiltration of the pia, and that he believes that there is no acute manifestation of syphilis of the cerebrospinal axis without it This author examined sections from eleven cases diagnosed clinically as tabes, and found in all lymphocytic infiltration of the pia, this being marked in nine cases He quotes Bresowsky, who found this picture constant in forty cases of tabes Schroder[7] found in all of five cases studied a pial inflammation of inflammatory nature

I may mention here the studies of Leri[8] on optic atrophy in tabes, in which this author believes that the pathologic process is an interstitial neuritis of the optic nerve due to syphilitic meningitis and syphilitic vascular disease, and the contribution of Vincent,[9] who studied the degenerations of the third, ninth, tenth, eleventh and twelfth pairs of cranial nerves in tabes and found, in the sense of Nageotte, a transverse radicular neuritis at the place where these nerves are included in the dural and arachnoid envelopes

I am inclined to favor the opinion that the cause of the tabetic degeneration is a radiculitis subsequent to primary syphilitic meningitis, believing that this meningitis is sufficient to explain the posterior root degeneration Whether this meningitis affects posterior roots in the locality favored by Obersteiner and Redlich,[10] or by Nageotte,[11] although interesting from the histopathologic point of view, is of secondary practical importance the important point to my mind is whether or not the tabetic process starts as an active inflammatory one in the meninges The importance of a clear understanding of this question is primary, not alone on account of the great diagnostic importance of an inflammatory cerebrospinal fluid, but also from the standpoint of local intraspinal injections by specific remedies

SYMPTOMATOLOGY

As a basis for a clinical study of the early tabes, I have selected and tabulated thirty-five cases from a total of 150 studied, 119 of these cases being similarly tabulated Tabulated cases cannot be recorded as completely as separate case reports, but this table presents in graphic form the most prominent features of early tabes The following discussion is limited to certain of these features, for the general symptomatology, further reference may be made to the table This list of early tabes is manifestly too small to be of value as a statistical study as regards sex, age, occupation, nationality and the incidence of syphilis as an etiologic factor, but it may be mentioned in passing that in this list of thirty-six cases, sixteen patients denied syphilitic infection Of this number the Wassermann was negative in the blood or cerebrospinal fluid in only six cases In this series of six cases, only two (Cases 13 and 36) showed an absence of pupillary signs—Argyll Robertson pupils, anisocoria, and pupils of irregular contour, which we have come to regard as characteristic in syphilis

Sensibility—Among the complaints, some kind of pain was the most frequent Under the headings of lancinating pains and pains described as rheumatism, we group the greatest number of these symptoms, our records show that only three cases — these all being cases of pronounced optic atrophy — gave no history of pain or paresthesias Headache was a common symptom, being present in ten cases Passing from the subjective complaint of pain to the objective disturbances of sensibility, we have grouped these disturbances under the headings deep and superficial sensibility I shall not detail the results of these examinations, nor are they tabulated, reserving this study for a future communication The frequency of objective sensibility disturbance is parallel with the severity of the disease, and these disturbances are probably a constant symptom in tabes, negative results being due to the inefficiency of our method of examination There appears to be no constant relationship between the presence of a positive Romberg symptom and a disturbance of the deep sensibility notion of position, passive motion, localization, deep pressure sense, discrimination between two points and the vibration test The loss of deep pressure pain brought out in Abadie's sign and Biernacki's sign was frequently present Occasionally in testing for Abadie's sign hyperesthesia was present

Superficial Sensibility The radicular disturbance of the cutaneous sensibility noted by Leyden, Marie, Dejerine, Redlich, Massary and Brissaud has been particularly studied by Marinesco,[12] and by Patrick[13] in this country with reference to tactile anesthesia about the trunk We have also noted the sensory involvement about the trunk and especially the increased sensitiveness to cold, and the girdle sensation Ulnar paresthesias, diminished sensibility about the genitals and the anus has also been noted in our cases In the lower extremities, however, the radicular disturbance of the sensibility has been in our experience less evident, in this locality the charts show a picture commonly seen in polyneuritis, or that described as a segmental distribution involving the feet and shading from the distal to the proximal end of the member Marinesco[12] previously called attention to this point The more frequent involvement of the superficial sensibility than the deep would be the opposite of what was to be expected in an involvement of the posterior columns of the cord only, which are not tracts for pain The symptoms of pure posterior column involvement seen best, according to Dejerine,[14] in combined sclerosis, is not the picture here We believe the frequency and constancy of pain in tabes one of the most convincing proofs of the radicular or meningeal cause of the disease

Reflexes—I wish to call attention particularly to the state of the tendon reflexes in the lower extremities, the tendon reflexes in the upper extremities being generally conserved in our series contrary to the opinion held by Frankel Preservation of the patellar tendon reflex and the Achilles tendon reflex is compatible with a diagnosis of tabes in thirteen of our cases such a condition was present The loss of the patellar tendon reflex or Westphal sign is properly considered an important and characteristic symptom of tabes I wish particularly to discuss the state of the Achilles tendon reflex in these early cases Babinski[15] (1901) deserves the credit of calling attention to the early loss of this reflex, which he claimed generally disappeared before the patellar tendon reflex During the period 1898-1901 this author observed forty cases of this nature, as opposed to five cases in which the patellar tendon reflex was absent and the Achilles tendon reflex present Prior to Babinski's publication, Goldflam[16] noted the absence of this reflex in cases of tabes, and Ziehen[17] discussed its diagnostic signification in various psychoses and psychoneuroses Following Babinski's first communication in 1898, C K Mills[18] found this reflex present in only three cases of tabes out of twenty-eight cases, in all of which the patellar tendon reflex was present Van Gehuchten,[19] Biro[20] and Tumpowski[21] arrived at similar results Kollartis[22] found eleven cases in 100 in which the Achilles tendon reflex was lost and the patellar tendon reflex conserved, and in only one case was the opposite the case Achilles tendon reflex present, patellar tendon reflex absent (unilaterally) Sarbo,[23] in ninety-two cases, found 91 per cent missing Achilles tendon reflexes, and in 190 cases 80 4 per cent missing patellar tendon reflexes In seven cases the Achilles tendon reflex was lost, the patellar tendon reflex conserved Forster[24] and Strassburger[25] noted the absence of this reflex in tabes, without, however, calling attention to its relative importance Bregman[26] draws an analogy between the loss of this reflex and cutaneous sensibility disturbances in the area supplied by the fifth lumbar and first sacral roots Oppenheim[27] sounds a warning note against attaching too great importance to the absence of this reflex in the diagnosis of tabes, because of its frequency in sciatica and related peripheral nerve conditions Jelliffe and White[28] state that the Achilles tendon reflex is not infrequently lost before the patellar tendon reflex

The technic of eliciting this reflex is important, the kneeling position with the foot hanging free and relaxed being necessary for a proper performance of the test (Babinski) In our series there were twenty cases in which one or both of the Achilles tendon reflexes were absent with conserved patellar tendon reflexes, and in seven of these, the Achilles tendon reflex was absent on one side only A striking relationship in regard to the absence of this reflex was seen in ten cases of primary optic atrophy, the extremities of the cerebrospinal axis, as it were, being affected by the tabetic process It would then appear that the loss of the tendon reflexes in the lower extremities in tabes takes the form of a regular progression from below upward in the majority of cases, and in this regard Cases 33 and 36 seem to show both Achilles tendon reflexes lost before the patellar tendon reflex, the latter reflex being lost first on one side only Further, in reviewing the total number of cases (150) we have encountered only one instance in which the patellar tendon reflex was absent when both Achilles tendon reflexes were conserved, and in this one instance only one patellar tendon reflex was lost From these data, then, we believe that as a rule the loss of the Achilles tendon reflex precedes the loss of the patellar tendon reflex, and is therefore an earlier and more important diagnostic sign It is possible in the cervical type of tabes that a different order may ensue, but such an example has not yet come under our observation

[28] Jelliffe and White Diseases of the Nervous System 1915

In our cases we note bladder disturbance in ten cases, a very important early sign of cord involvement, also gastric crises in ten cases The frequency of general glandular enlargement including epitrochlear enlargement (eleven cases), and cardiovascular disease is called attention to because they are important symptoms of syphilis and not of tabes In fifteen cases psychic or neurotic disturbances were noted

Eye Symptoms—The frequency of eye symptoms in tabes has long been recognized, and among these, primary optic atrophy is probably the most frequent The remarkable statistics of von Grosz[29] show 88 per cent of diseased papillae in 100 cases examined, and in only two out of the twelve normal backgrounds were present normal vision, normal fields and normal color perception In thirteen of our tabulated cases primary optic atrophy was found, being quite advanced in a number of these cases From the study of these we were able to pick out many of the early forms of tabes enumerated here Argyll Robertson pupils and those showing definite sluggish reaction to light were present in twenty-four out of twenty-five cases, and anisocoria and pupils of irregular contour were found, respectively, in fifteen and thirteen cases, which establishes these two conditions as of great importance as characteristic tabetic eye signs possibly antedating the Argyll Robertson pupil

Ear Symptoms—There were sixteen cases of diminished hearing, nine of these in association with optic atrophy The absence of special examinations in all cases to determine the character of the deafness, whether a nerve deafness or of peripheral origin, is of course not conclusive, but recent observers, such as Knick and Zaloziecki[30] and Swift,[31] who called attention to syphilitic meningitis as the cause of diminution of hearing in certain cases of early syphilis, is important in suspecting a large percentage of our cases to be due to nerve deafness, consequent on radicular nerve disease The fact that syphilitic disease of peripheral nerves is a very rare disease would support this view

Trauma—In eleven cases a history of trauma was obtained The question of trauma as an exciting cause or a contributory cause in tabes in relation to disability has come up in industrial accident cases in California An analysis of these eleven cases shows four patients (Cases 1, 10, 24 and 31) were injured before syphilitic infection took place In two other cases (Cases 16 and 26) of failing eyesight and optic atrophy, trauma preceded the failing eyesight by so short a time that its role in the development of the optic atrophy was very questionable

Wassermann Reaction and Cerebrospinal Fluid Analysis—The Wassermann reaction was found positive in twenty cases in the blood and in twenty cases in the cerebrospinal fluid, and in one or both in twenty-seven cases The globulin reaction was present in twenty-two cases out of the thirty-one done The cell count was positive in twenty-seven out of thirty-two cases and was the most frequent positive cerebrospinal fluid reaction in our series In five cases the cell count was not increased, three cells being regarded as the upper limit of normal per cubic millimeter In a recent paper[32] on the subject of cerebrospinal fluid analysis in which 116 fluids were examined, it was my opinion that six cells per cubic millimeter were the upper limit of normal, but we have come to regard this figure as too high The lower figure corresponds with the results of Nageotte, who found an average of three cells per cubic millimeter in fifty-six normal fluids examined I myself prefer the Nageotte[33] counting cell, and count at least six cubic millimeters of fluid, making two separate spreads and being careful to obtain a good admixture of fluid and to count the fluid a short time after it is withdrawn It is exceedingly likely that variation in results is often due to a failure in technic In three cases the cells and globulin were not increased, and in two cases all reactions of the cerebrospinal fluid, including the Wassermann test, were negative Nonne[34] reports eleven such cases in 167 cases of tabes In Case 13 we have a record of an entirely negative cerebrospinal fluid with definitely thickened membranes

This brings us to the consideration of the importance and constancy of the cerebrospinal fluid reactions indicating inflammation increased cell count and increased globulin content and probably also the Lange gold test Since Widal, Sicard and Ravaut[35] found an increased cell content in cases of paresis and tabes, and Guillian and Parant[36] noted an increased globulin content, these tests have occupied first rank as important diagnostic aids in detecting syphilis of the central nervous system In the Paris meeting noted above it was the opinion of Sicard that a lymphocytosis was constant in tabes as a rule Soques had found it absent one or two times in tabes Andre Leri considered the lymphocytosis as indicating a meningeal process in evolution, and reported on the examination of a spinal cord in which at different levels the histologic picture varied, in the cervical region thickened membranes and infiltration of leukocytes, whereas the dorsal cord showed definite thickened meninges without infiltration of leukocytes

This brings us to the important point of correlating our findings in the cerebrospinal fluid with our conception of the histopathology of tabes dorsalis We have seen in our list of necropsies that a chronic syphilitic leptomeningitis, most intense in the posterior aspect of the cord, is a constant finding It would be only natural to assume that such an inflammation in the meninges would manifest itself in increase of cells and globulin in the cerebrospinal fluid I believe that repeated lumbar puncture will show at one time or another increased cell count and albumin in a progressive tabes, and that in a negative outcome of such repeated tests the diagnosis of tabes should always be made with reserve It may not be amiss to report a case[37] previously but erroneously reported as tabes, which presented certain characteristic symptoms of tabes gastric crises, ataxia, sensory disturbances and absent Achilles tendon reflexes and patellar tendon reflexes Repeated examinations of the cerebrospinal fluid were constantly negative as regards cell count and globulin, but finally a faintly positive Wassermann reaction in the cerebrospinal fluid was obtained Syphilis was denied This patient subsequently died of an intercurrent affection, and necropsy revealed posterior column degeneration on cut sections of the cord which led to the diagnosis of tabes dorsalis, but the meninges were not thickened or infiltrated This feature was commented on, and this was considered a case worthy to report, but Weigert's stain for myelin degeneration showed the typical picture of a combined sclerosis I am not aware of any case of tabes being yet reported which has shown clinically a negative cerebrospinal fluid finding for cells or globulin, and in which a following postmortem examination has revealed normal spinal meninges by microscopic examination

CONCLUSIONS

1 In tabes the syphilitic posterior leptomeningitis of the spinal cord (and probably also of the radicular nerve) is in etiologic relationship to the degeneration of the posterior columns of the cord Every case of syphilitic posterior leptomeningitis and consequent multiple symmetrical radiculitis is a case of potential tabes

2 This meningeal reaction is evidenced in the cerebrospinal fluid by an increased cell count and increased globulin content, and probably also by a positive Wassermann reaction indicating that this reaction is syphilitic in nature During certain stages in the evolution of tabes, probably of repair, these reactions may be negative It is therefore necessary to make repeated lumbar puncture in doubtful cases

3 Syphilitic radiculitis has its characteristic disturbance of the sensibility Subjective disturbances are pain and paresthesias, objective disturbances are deep and superficial sensibility impairment, the latter following radicular distribution In the lower extremities, this radicular involvement cannot always be demonstrated, the sensory cutaneous involvement often presenting a peripheral or segmental type

4 The Achilles tendon reflexes are lost as a rule before the patellar tendon reflexes this phenomenon was observed in ten cases of primary optic atrophy from a total of thirteen cases

5 Anisocoria and pupils of definitely irregular contour are found frequently in early tabes These pupillary signs, even in the absence of the Argyll Robertson pupil, are highly characteristic of early tabes, provided there is no local assignable cause

6 The symptom of diminished hearing is frequently encountered in early tabes

7 Cardiovascular disease, especially aortic disease, and general glandular enlargement are frequently found in tabes, thus giving evidence of syphilitic processes elsewhere in the body

8 In a patient with a history or other evidence of syphilis presenting characteristic sensibility disturbances of the radicular type with a tendency to symmetry, one should suspect a potential or early tabes If, associated with the foregoing, we have a positive reaction in the cerebrospinal fluid indicating a chronic syphilitic meningitis, together with such pupillary phenomena as anisocoria, pupillary irregularity or sluggish reaction to light, the diagnosis of early tabes is most probable Added to the foregoing symptoms, the loss of the Achilles tendon reflex establishes the diagnosis of early tabes even in the absence of those signs which we usually associate with tabes Romberg, marked sensibility loss, absent patellar reflexes and Argyll Robertson pupils

SHALL WE TREAT THE PARETIC?*

C EUGENE RIGGS, M D

AND

E M HAMMES, M D

ST PAUL

The first clear presentation of the clinical relationship of the mental and physical symptoms in paresis was made by Bayle in 1822, although the earliest description of this disease was given toward the close of the eighteenth century by Chiarugi and Haslam[1] Almost forty years ago, Fournier startled and antagonized the medical world by suggesting that syphilis in the great majority of cases was the cause of locomotor ataxia This has been a subject of bitter discussion for more than a third of a century, in fact it was Metchnikoff's infection of apes with syphilis in 1903 that robbed syphilis of its mystery, and gave it a definite standing among infectious diseases This was the first definite step in the elucidation of our present knowledge of the pathology and symptomatology of nervous syphilis Then came notable years Schaudinn in 1905 discovered the *Spirochaeta pallida* In 1906, Wassermann announced his reaction, which proved the presence of syphilis in the varied manifestations of syphilis The researches of Noguchi, Moore, Marie and Levaditi, who have found spirochetes in the lesions of tabes and paresis, demonstrated that *in these affections*, we are dealing with actual syphilis a late manifestation of the infection It has been recently suggested that we discard the terms "paresis" and "tabes," and speak only of cerebrospinal syphilis, paretic or tabetic in type The yearly economic loss to New York State on account of insanity is about $35,000,000 Syphilis was the principal cause of insanity in 19 8 per cent of the male and in 7 2 per cent of the female patients admitted to New York State hospitals in 1913 "Of the killing diseases," says Sir William Osler, "syphilis comes third or fourth." Church states that it is a conservative estimate that one man in every five is syphilitic In the New York State hospitals, paresis constitutes one eighth of all the admission Out of 4,000 syphilized men examined, *twenty-two years after the last of them was infected*, Mattauschek and Pilcz[2] found that 6 27 per cent had developed paresis or tabes or both of these diseases It has been estimated that from 9 to 25 per cent of those infected develop nervous symptoms At the San Francisco session of this Association, we placed great emphasis on the importance of the examination of the spinal fluids in early syphilis Hoffman, Nicols and Steiner have observed that in 15 per cent of the cases in primary and secondary syphilis, the spinal fluids are infectious, and infections by their inoculation can be obtained before changes can be observed in the Wassermann and other reactions[3] After a syphilitic infection, it would appear that there is invariably an involvement of the central nervous system, even though it be of slight duration and unattended by neural change That a variation in the spirochete occurs is shown by laboratory experiments Wile[4] observed that spirochetes injected into rabbits from the living paretic brain were of a virulent type, and that the incubation was shorter than with other strains Investigators in the laboratory of the Army Medical School in Washington have bred several varieties of spirochetes "They can breed a variety which will produce a hard chancre, or a variety which will produce a chancre lacking the old hunterian characteristics of a saucer-like indurated base They can produce a spirochete which will give a mucocutaneous efflorescence, or a spirochete which will be poor in cutaneous manifestations, with a tendency to confine its influence to the nervous system" (Church)

---

* Read before the Section on Nervous and Mental Diseases at the Sixty Seventh Annual Session of the American Medical Association, Detroit June 1916

[1] Chiarugi and Haslam, quoted by Kraepelin General Paresis Nervous and Mental Diseases Monograph Series No 14 1913

[2] Mattauschek and Pilcz Ueber die weiteren Schicksale 4 134 katamnestische verfolgte Falle luetische Infektion, Med Klin 1913, p 1544

During the past decade, our conception of syphilis and its therapy has been absolutely revolutionized The latter was based largely on hypothesis and empiricism Twenty-seven years ago, we were taught that the essential and primitive anomaly in the paretic's brain was "a vasomotor disturbance"[5] Trephining was therefore suggested by Batty Tuke of Edinburgh, to overcome cerebral congestion and we (Dr Riggs) can well recall the enthusiasm with which he discussed the potentialities of the new procedure This was the first step in the subdural medication of today In 1901, Dr Ford Robertson,[6] suggested that paresis was a disease due directly to the toxins of bacteria, the point of attack being the alimentary tract In 1903, he first announced his theory of *Bacillus paralyticans* as a cause of dementia paralytica[7] In 1905, Robertson and McRae[8] reported the presence of the diphtheroid bacilli in the genito-urinary tract in general paralysis and tabes dorsalis The same authors,[9] in 1907, discussed the treatment of paresis and tabes by vaccines and antiserum While they first tried vaccines, they placed their reliance on the antiserum The latter was obtained from immunized sheep which had been inoculated with dead cultures of the *Bacillus paralyticans-longus*, isolated from the brain of a general paralytic After two months' treatment of the sheep, the serum was fit for use It was administered by mouth, nose or hypodermic Of twelve cases of paresis treated by them they report that "all have shown remarkable signs of improvement" In tabes the ataxia was much benefited

The favorable influence of an intercurrent acute febrile disease in certain cases of general paralysis has long been a matter of common observation Since it would be neither judicious nor wise to infect the patients with a serious specific fever, other means for inducing a harmless temporary febrile reaction have been suggested The tuberculin treatment of von Wagner[10] and the sodium nucleinate injections of Donath are the two classical methods of inducing artificial pyrexia in this disease In 1909, von Wagner announced his treatment of general paralysis by injections of tuberculin (Koch) combined with mercurials and iodids His pupil, Pilcz, in 1910-1911, reported eighty-six cases of clinically demonstrated paresis which were treated by this method Small doses, from 0 0005 to 0 01 c c of tuberculin, were injected every second day, the dose being gradually increased until 0 3 or 0 5 or even 1 c c was administered In 39 44 per cent there was no perceptible or only a slight improvement, while in 60 32 per cent there was a distinct clinical betterment observed Remissions were noted in 26 per cent of the cases In 1903, Donath[11] reported six cases of paresis and of cerebral syphilis treated by salt infusion, given every third or fifth day The infusion was administered for the purpose of freeing the system of toxins formed by the degenerating nervous substances All these patients were improved by the treatment, and he believed the subcutaneous injections of salt solution of particular value in early paresis In 1910, he suggested the use of sodium nucleinate in place of the salt infusion[12] He injected 1 gm of this salt (a 2 per cent solution in normal saline) once a week There is a rise of temperature, which attains its maximum in from four to ten hours and returns to the normal in from one to two days, a transient leukocytosis numbering from 10,000 to 25,000 per cubic millimeter occurs, which disappears generally by the fifth day He reported the treatment of fifteen patients with paresis, 60 per cent showed improvement in tremor and memory and a lessening of acute mental symptoms, three were able to return to work, six were improved, in five there was no change, one died of apoplexy Mercury was also used

Last fall, we (Dr Riggs) wrote twenty-six of our leading neurologists and alienists in regard to their experience with the pyrexia treatment in paresis None had used tuberculin, two, Dr Dana and Dr Barrett, had tried the sodium nucleinate injections The former stated that he had used the nucleates of soda in several cases of paresis He had not seen it do any good and had not heard of any good results The latter wrote "We did a little work with the nuclein treatment of Donath, but our work was not carried very far I felt that with such methods as these we could not get at the real root of conditions present in paresis" In Dr Church s reply, he said Many years ago (twenty-five years) some such cases were treated with inoculations of modified erysipelas germs, or what amounted to that, in the hospital at Elgin, only, however, with unfortunate results" Regarding this method, Dr Purves Stewart says "I have made a number of observations with a moderate amount of encouragement" Dr C W Burr questions the beneficial influence of an acute febrile attack in these patients "I have seen a few patients, who, during a febrile attack, seemed to temporarily improve My impression is that the cause of the fever was of no importance I have never seen any permanent good result I have seen many other patients with paresis in whom fever had no influence at all"

In 1905, Dr Myer[13] said, "The important point about general paresis seems to be finding out what makes general paresis a progressive disease" Modern research answered that question The important problem now is how to destroy the spirochete The potentiality of our therapeutic resources has been greatly enhanced by Ehrlich's discovery of salvarsan in 1909 It is the consensus of opinion that all the varied manifestations of syphilis can best be treated by the combined use of mercury and salvarsan Since these patients first consult the general practitioner, on him rests a grave responsibility, for only by an early recognition of the initial lesion and a radical use of modern methods of therapy can a cure be obtained, or late syphilis (paresis or tabes) be prevented After invasion of the nervous system, one of two modes of procedure may be advised intrathecal or intensive medication To Marinesco, in 1911, belongs the credit of the initiation of the former Swift and Ellis used salvarsanized serum intraspinally in the therapy of tabes dorsalis in 1912, while Robertson of Edinburgh employed it in paresis in 1913 In 1914, Ravaut injected neosalvarsan directly into the spinal fluid Byrnes during this year used intraspinal injections of mercurialized serum In 1915, Hammond and Sharpe treated three paretic patients by direct injection, into the lateral ventricles, of salvarsanized serum and neosalvarsan added to the serum

This multiplicity of procedure is not chaotic, as it would at first appear, it is an expression of the scientific purpose to reach the hitherto inaccessible spirochetes, to bring the spirocheticidal solution into contact with the infecting organism, it is simply science groping, if somewhat blindly, for a definite result "The end in view in this treatment of nervous syphilis," says Swift, "is threefold, i e, cure, amelioration or prolongation of life" Have modern methods, as employed in paresis, been of value in any of these respects? Certainly not in cure in fully developed types of the disease Do they arrest or favorably influence paresis or prolong life? Many believe that as good results were obtained from the routine treatment of the presalvarsan period Others regard modern methods as most disappointing Evans and Thorne[14] state that as much improvement may be seen in patients who have received no special treatment as they observed in their cases following the combined use of the intraspinal and intracranial methods Such, however, has not been our observation or experience

We believe that, by intraspinal medication, remissions are greatly increased in frequency, that in early paresis, marked improvement may occur, with a possible arrest of symptoms Paine[1] has observed 1,279 untreated cases in which there occurred ninety-five remissions Statistics vary greatly as to their occurrence, varying anywhere from 4 to 20 per cent Cotton has observed as the result of treatment 35 5 per cent of remissions, while in the untreated cases, the number of spontaneous remissions was about 4 per cent Ogilvie[16] has reported twenty-six remissions, averaging over a year each, out of thirty-five cases The minimum number of injections required to induce a remission was six, the maximum, fourteen "The establishment of a remission," says this writer, "is something gained, but it is merely one step in the right direction" The favorable results of this treatment, according to Amsden, can best be expressed in terms of remission "The value of remissions in general paresis in any line of treatment is difficult to estimate," says Barrett "We have, however, gained the impression from a considerable amount of work, that remissions are more complete and patients are able to remain out of the institutions longer when treated intraspinally than by any other mode we have used"

Regarding the arrest of the paretic process, Marinesco and Minea[17] say

> Modern therapeutics cannot accept the dogma of the incurability of general paresis, not even of its steady progress, there are cases known where the disease is stationary, such are rare There are many cases in which repeated remissions occur The stationary state, as well as the repeated remissions, prove not only that the lesions can stop for some time but also that there must be in the brain of general paralytics alterations which can be replaced

These writers suggest that remissions are due to the formation of antibodies as in other infectious diseases

We have had the opportunity of observing seventy-one cases of paresis during the past four years, of which twenty-one have been treated by us Of the fifty untreated cases, or those treated intravenously or with mercury one only has had a remission The brief citation of four cases will be sufficient

Case 1—Man The grandiose type, with characteristic spinal blood and fluid findings of paresis A remission of four months duration occurred after the sixth treatment A relapse occurred and after further treatment there was a second remission of five months' duration, which still persists He is steadily improving and is practically normal aside from occasional periods of mild elation This patient has had forty-one intraspinal injections (thirty-four salvarsanized serum seven mercurialized serum) with no untoward symptoms The spinal fluid gives a positive Wassermann in 0 8 c c, there is a trace of globulin, no lymphocytosis, blood Wassermann negative, no change in the colloidal gold reaction

Case 2—Man aged 44, family and personal history negative, aside from alcoholism Acute grandiose type, patient showed mental unbalance a year before coming to us Biologic findings typically those of paresis, remission took place after the seventh injection, which lasted for eight months He was able to resume the oversight of his business affairs He then became homicidal and suicidal and was sent to the state hospital Aside from the suicidal propensity, his mental condition seems good He received twenty-one injections of salvarsanized serum (Swift and Ellis), blood Wassermann negative, spinal fluid negative in 0 8 c c, positive in 1 c c no globulin, no lymphocytosis, colloidal gold curve uninfluenced

Case 3—Man, aged 48, single, gonorrhea in 1900, denied syphilis, when seen by us he was acutely excited, it required four men to bring him to the hospital Since January, 1915 patient has been indifferent about his work and restless He became elated in March, 1915 There were Argyll Robertson pupils and increased knee jerks Serobiologic findings those of paresis After the sixth injection of salvarsanized serum, he was able to return home and help on the farm At present writing aside from slight nervousness, he is apparently normal He received in all twenty-six intraspinal treatments (Swift and Ellis) After a time, we gave him weekly, in addition, 2 grains of mercuric salicylate intramuscularly. Blood serum is negative, spinal fluid positive in 0.8 c.c., no lymphocytosis, no globulin, colloidal gold curve unchanged.

[17] Marinesco and Minea L'emploi des injections de serum salvarsanisé in vitro et in vivo sous l arachnoid spinale et cerebrale dans le tabes et la paralysie generale Rev Neurol *1914* **27**, *337*

Case 4.—Man, aged 38, contracted syphilis in 1902, consulted us, March, 1916, was talkative, disoriented, very restless, expectorated constantly and made grimaces, Argyll Robertson pupil, increased knee jerks and Babinski. Biologic findings those of paresis, was given mercurialized serum intraspinally with intramuscular injections of mercury. He grew gradually worse and died, April 1916. No biologic reduction. Evidently this was a case of so-called "galloping paresis."

Of the twenty-one patients treated with salvarsanized serum intraspinally (Swift and Ellis) with and without mercury intramuscularly, ten showed a decided improvement. Of these, five are at present attending to their business affairs, one had a remission of eight months, another one of four months, one has had two remissions of four and five months' duration, respectively, one is at home. In this patient, there is a slight improvement with an occasional epileptic attack. Still another is home and is able practically to attend to his business. Three died, not following an injection, but some time after discontinuing treatment. The eight remaining are still living and have manifested some improvement physically, but no change in the mental condition. In all but two of these patients who were sufficiently treated, the Wassermann in the blood became negative, but none gave a negative Wassermann in the spinal fluid, lymphocytosis disappeared, globulin a trace. We have been unfortunate that in none of our cases have we been able to render the spinal fluid negative. According to Ogilvie, it is practically impossible to get a negative Wassermann in true parenchymatous disease of the brain. When obtained, it indicates that the specific process is confined largely to the interstices of the cerebral tissues.

"At this hospital, we have treated, in all," says Dr. Blumer,[18] "twenty-five cases, twenty paretics and five tabetics (December, 1915). Of the paretics, five are now dead, four having shown no improvement, one died of a convulsion after having shown considerable improvement. In five other cases, the course of the disease continues unabated. The remaining ten have all shown great clinical improvement and have been able to return to their homes and business. Of these, three men have had no recurrence during nearly two years' absence from the hospital. The laboratory results have been rather discouraging. Only four patients have obtained a persistently negative Wassermann. Most of the others show no change, while in some the Wassermann has appeared and disappeared irregularly. Three show disappearance of the gold chlorid reaction, while the remainder show practically no change. In all cases the cell count has shown a steady reduction, the globulin content has been more varied, but in most cases has fallen to normal with the improvement of the patient." "We have a number of cases of paresis," writes Barrett, "who were treated intraspinally, in which the diagnosis was unquestionable, who are now carrying on their accustomed occupations with remarkable efficiency, considering their disease."

Amsden[19] states that "intraspinal treatment with salvarsanized serum has in a considerable number of cases a positive influence in checking the progress of the disease, at least clinically, it does not stop it except in very rare cases." The writer also calls attention to the fact that from the standpoint of the family the value of this treatment is a matter of importance, since the patient may become able to give information about his affairs, enabling him, as it were, to put his house in order. "In the use of salvarsanized serum," Cotton says, "we have an agent which does cause definite arrest in paresis, which arrest includes improvement in the clinical symptoms, physical signs and a corresponding change in the biological reactions from positive to negative." The writer points out that as it is necessary to treat tuberculosis in the incipient stage in order to obtain results, that it was equally true in regard to paresis, it was fallacious to condemn the treatment of paresis because we could not cure the end stage. He says:

> The emphasis should be placed on treating the cases early. This is especially so in regard to state hospital work, where 75 per cent. of the cases are admitted too late for treatment to be of any benefit to them, but 25 per cent. can be materially improved, as shown by our records. The mortality from paresis has dropped 33⅓ per cent. in the hospital in the last three years. We also have no bedridden paretics, which as a rule are the bane of most hospitals. If these results can be produced on fairly well advanced cases, it augurs well for the success of the treatment of early cases.

The time, then, of greatest opportunity in the treatment of paresis is in its incipiency, before the parenchyma of the cortex has become the seat of degenerative change. "It would be unfortunate," says Amsden, "if apparent poor permanent success in arresting the disease should keep us from trying it and trying to improve it." We are in entire accord with Ogilvie when he says that intraspinal treatment is entitled to recognition as a rational therapeutic procedure and that a far greater percentage of all kinds of cases respond to it than to the older methods of therapy. We have persisted in the use of the Swift and Ellis procedure because there is less hazard in its use, and therapeutically it is as efficient as any. Ayer[20] has described intraspinal injections of serum under prolonged high pressure. He has been able to demonstrate the serum in the subarachnoid space over the frontal lobes. It is possible that this method may possess an increased curative value. Mercurialized serum has given us good results, although it has seemed somewhat more irritating than salvarsanized serum. Several times the injection has been followed by incontinence of urine. We have not employed cerebral puncture as suggested by Wardner,[21] there is much to commend it, and in cases of paresis of long standing it is perhaps the method to be chosen. It is certainly preferable to ventricular puncture as suggested by Hammond and Sharpe. The employment of Ogilvie's standardized serum is a conservative means of injecting salvarsan directly into the spinal canal. Its beneficial effect cannot be doubted. Cotton is using this method for cerebral puncture and mercurialized serum for both cerebral and intraventricular puncture. While the value of drainage of cerebrospinal fluid cannot be explained on theoretical grounds, yet benefit has, in our observation, followed this procedure in some hitherto intractable cases. Sachs believes that he has seen as marked and satisfactory improvement from intravenous as from intraspinal therapy, and he has come to feel that the latter has been unduly pushed; it is more difficult to give, more likely to lead to serious complications, and at times it has been followed by disastrous consequences. Cotton says he considers intravenous injections of salvarsan more dangerous than intraspinal; that with myocardial trouble the former might prove fatal. He says:[22]

> We have given as near as I can figure about 3,000 treatments in the last three and a half years, and have had no unfavorable results whatever, except one or two cases have developed an irritative meningitis which subsided within a week without any bad results.

Ogilvie states that the use of his serum "in more than 1,800 treatments has shown it to be both safe and effectual as a curative agent in types of syphilitic nervous diseases, in which intraspinal therapy is indicated." We have made over 600 injections of salvarsanized serum (Swift and Ellis method) with no serious ill effects. *In one patient only, there developed* an aseptic meningitis, which quickly subsided. Our experience teaches us that this method is a safe and conservative form of therapy, and should be preferred to intensive medication in all serious cases of cerebrospinal syphilis and its late manifestations, paresis and tabes. Over 74 per cent of Ogilvie's series of cases were influenced favorably to a degree not attained by the most heroic intravenous treatment, either with or without mercury.

CONCLUSIONS

1. Both clinically and biologically it has been demonstrated that treatment is a material benefit to the paretic.

2. Before the salvarsan era, the number of remissions varied from 4 to 20 per cent. Since its use and the employment of modern forms of therapy, they have been greatly increased in frequency.

3. Treatment, to be effective in paresis, must be given in its earliest stage; in cases of long standing it is useless; cell destruction cannot be replaced. Also, to be effective, it must be persistent. It may be a matter of many months before the activity of the infection can be influenced.

[22] Personal communication to Dr. Riggs.

A Warning Against Trichinosis.—The federal meat inspectors do *not* inspect pork or pork products to determine the presence or absence of the organisms causing trichinosis, as even careful microscopic examination is unreliable. They do require, in establishments under their supervision, that pork that is to be made into products to be eaten raw shall be heated or subjected to extreme cold so as to destroy such organisms, but as federal inspection covers only establishments engaged in interstate commerce, it is not safe to rely *on it* altogether. Even such products should be avoided unless they are known to have come from establishments under federal or equivalent inspection. In fact, the Bureau of Animal Industry, United States Department of Agriculture, in a warning just issued against the danger in raw pork, gives no countenance to its use as an article of diet, but emphatically sets forth that the safest plan is to eat no pork products of any kind raw. According to the bureau, the records show that the number of cases of trichinosis increases during the holidays, partly because of hog-killing time, and partly because farmers frequently make up special forms of sausage which are eaten without cooking. The rule of safety laid down by the bureau is to cook pork until it has lost its red color throughout all portions, or, if a trace of this color is still present, at least until the fluids of the meat have become more or less jellied.

Therapeutics

DISTURBANCES OF THE KIDNEYS

(*Continued from page 120*)

CASTS

There are several kinds of tube casts: (1) hyaline, (2) epithelial, (3) blood, (4) granular, (5) fatty, (6) waxy or amyloid, and rarely (7) bacterial. Cylindroids formed from so-called mucus are shorter and broader than hyaline casts, but are less firm in structure, being readily broken up. They are of no significance except when they occur in considerable numbers, when they indicate kidney irritation and an abnormal increase of mucous secretion. Cylindroids and hyaline casts are formed from the same substance as that which forms the mucous threads sometimes found in the urine.

1. A hyaline cast is a secretion of this mucus, perhaps by the glomerulus, which has remained in a tubule until it has become formed and shaped, although its size may not represent the region of the kidney from which it comes, as the tube may have become dilated. Most hyaline casts probably come from the Henle loops. Albumin passing through the glomeruli may also coagulate and form hyaline casts. It is probable that a hyaline degeneration may occur in certain pathologic conditions and in acute infection of the epithelial cells of the tubules, and hyaline casts be thus formed. Both cylindroids and hyaline casts are more likely to be found in concentrated and acid urines, as low specific gravity urine and neutral and alkaline urines cause disintegration of these frail structures. Like cylindroids, hyaline casts indicate only kidney irritation and a sluggish urinary flow in some part or parts of the kidneys. Of course the freer the flow of urine, the shorter time will mucus or any other substance remain in the tubule.

High power microscopic examination shows hyaline casts to have many organized particles and not to be absolutely homogeneous.

Not only hyaline, but also epithelial and fine granular casts may be found in the centrifuged urine of normal persons, especially if this urine is first sedimented. However, they usually represent some slight kidney irritation. If hyaline casts are repeatedly found in the urine of the same person, particularly if he is over 40 years of age, and if there are traces of albumin, it may indicate the beginning of chronic interstitial nephritis; but it should be emphasized that hyaline casts can occur with physical strain, with mental anxiety and mental strains that would disturb general metabolism or the circulation, and with any acute infection, even the simplest.

2. Epithelial casts represent hyaline casts with loosened epithelium of the tubules, and the form of the epithelium may denote the region of the kidney in which the casts originated. Irritation or passive congestion may cause this type of casts to occur in slight disturbances, as well as in tubular nephritis.

3. Blood casts show acute kidney congestion or kidney hemorrhage, and are composed of blood cells and serum. Many epithelial, hyaline and finely granular casts may show both white and red corpuscles. Blood casts are most frequent in acute nephritis. When found in hematuria, they show that the bleeding, in part at least, is from the kidney structure. Even when in acute nephritis the blood casts are in large amount, they may not be of serious omen unless the patient is

uremic With signs of uremia and serious kidney congestion, the prognosis is unfavorable

All urines will contain some leukocytes and frequently red cells, which may come from any part of the tract However, unless the urine has been obtained by the ureteral catheter (without injury), or there are blood casts or blood cells in casts, it cannot be positively stated that these blood cells come from the kidney

4 Granular casts are degenerated epithelial casts When there is a diffuse nephritis and degeneration occurs in the epithelial cells of the convoluted tubules, more or less debris is thrown into the lumen of the tubules which, remaining there for some time, causes the production of granular casts, in the beginning, with fine and later with coarse granulations When, with degenerative disease of the epithelium of the tubules, there is a large amount of urine passed, the debris may not remain in the tubules long enough to form casts, consequently such urine, when centrifuged, will show epithelial and granular debris Also, long and rapidly centrifuged urines may have the granular casts broken down, forming debris

5 Fatty or oily casts represent fatty degeneration of epithelial casts They may be composed wholly of fat or of oil, or may be epithelial or granular casts containing oil globules due either to an infiltration or to degeneration of the cell contents They generally indicate a serious diseased condition, and occur when there is chronic nephritis of any type which has been of considerable duration

6 Waxy or amyloid casts are somewhat like hyaline casts, but show amyloid reaction They are not necessarily confined to amyloid infiltration or degeneration of the kidneys, but are signs of severe nephritis, and may be due to a degenerated blood coagulum They are either straight, bent or twisted, and represent molds of the convoluted tubules The hemorrhage may be from the glomeruli, the blood remaining in the tubules, or it may come directly from the walls of the tubules It should perhaps be emphasized that waxy casts do not necessarily denote amyloid disease of the kidneys

7 Serious kidney infection is sometimes accompanied by casts of bacteria in the urine However, before deciding that these casts come from the kidneys, one must be certain that the urine examined is fresh, as rolls of bacteria resembling casts frequently occur in old urine

Casts may come from one or more infected regions of the kidneys, but may represent an acute or chronic disturbance of just one portion They do not disturb the general function of the kidneys, though they must impair that of the parts affected In this relation we should bear in mind the great recuperative power of the kidneys

(*To be continued*)

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies A copy of the rules on which the Council bases its action will be sent on application W A Puckner Secretary

ACETYLSALICYLIC ACID—Acidum Acetylsalicylicum.—Acidum Acetylosalicylicum.—Aspirin—$C_6H_4O(CH_3CO)COOH$, 1 2—The acetyl derivative of salicylic acid

Dosage—From 0 3 to 1 Gm (5 to 15 grains), repeated once in three hours until symptoms of salicylism (ringing in the ears, etc.) are noted It may be administered in the form of a powder, wafers, or capsules If prescribed as a powder, this may be administered by dissolving it in sweetened water, or by placing it on the tongue followed by a swallow of water The powder should be dispensed in wax paper

Acetylsalicylic acid may be obtained by the condensation of acetyl chloride or acetic anhydride with salicylic acid and subsequent purification by recrystallization from chloroform or other suitable solvent

It occurs in small colorless crystals or as a white crystalline powder odorless of acid taste and reaction melting point from 134 to 136 C It is sparingly soluble in cold water gradually decomposing into acetic and salicylic acids rapidly decomposed by boiling water freely soluble in alcohol soluble in chloroform and ether also soluble with decomposition in solutions of alkali hydroxides and carbonates

When 0 5 Gm of acetylsalicylic acid is treated with 10 Cc of warm sodium carbonate solution (10 Gm $Na_2CO_3+H_2O$ in 100 Cc) a clear solution results

When 0 5 gm of acetylsalicylic acid is boiled for from two to three minutes with 10 Cc of 5 per cent sodium hydroxide solution and to the cooled solution 10 Cc of diluted sulphuric acid are added, a crystalline precipitate is produced which after washing and drying responds to tests for salicylic acid and the filtrate has the odor of acetic acid

If to a solution of 0 1 Gm of acetylsalicylic acid in 5 Cc of alcohol 20 Cc of water be added and then a drop of diluted ferric chloride solution (1 volume of ferric chloride test solution to 4 volumes of water) no violet coloration should be produced (salicylic acid)

When 0 5 gm is shaken with 25 Cc of distilled water for five minutes and filtered 5 Cc portions are not affected by hydrogen sulphide (absence of heavy metals) nor with silver nitrate solution (absence of chloride) nor with barium chloride solution (absence of sulphate)

When heated on platinum 0 5 Gm should leave no weighable residue

It should be kept in well stoppered containers

IOCAMFEN—A liquid obtained by the interaction of iodine 10 parts phenol 20 parts and camphor 70 parts, containing about 7 25 per cent free iodine

Actions and Uses.—Iocamfen is said to have the antiseptic and germicidal properties of iodine and also the analgesic, stimulating and antiphlogistic properties of camphor and phenol

Iocamfen is used especially in the treatment and dressing of surgical and traumatic wounds, joint injuries, fractures, infected processes contusions, etc

Dosage—Iocamfen is applied in small quantities directly to wounds, the skin cavities, etc or on tampons or drainage material It should not be applied to wet surfaces

Manufactured by Schering and Glatz New York No U S patent U S trademark No 112 934

Iocamfen Ampules—Each ampule contains iocamfen 20 minims

Iocamfen is a dark reddish brown viscid liquid having a camphoraceous odor Iocamfen is insoluble in water but soluble in all proportions in alcohol ether benzine and liquid petrolatum

Iocamfen like free iodine interacts with fats and waxes its free iodine entering into combination

The free iodine content of iocamfen may be determined as follows About 2 Gm iocamfen is weighed into a glass stoppered flask dissolved in about 25 Cc chloroform about 10 Cc potassium iodide solution (1 10) added and the free iodine determined by titration under agitation with tenth normal sodium thiosulphate solution using starch as indicator

Comparison of Rural and Urban Mortality—In an analysis of the figures shown in the new United States life tables based on the United States Census of 1910 and the mortality statistics for 1909 1910 and 1911 in the original registration states, J W Glover (*Public Health Reports,* Jan 5, 1917) says that the excess of city over rural mortality should receive the attention of health authorities to determine its cause and to what extent it may be reduced Out of 100,000 births of males in the country, 58,117 survive to the age of 60 while among the same number of city births only 43,454 survive to that age Glover says these figures are so astounding that they deserve the utmost prominence Recent life tables, it is said show similar differences in England and Germany The tables also show that the mortality rates among women are lower throughout the entire range of life than for men and that the expectation of life is much greater A striking exception is in the case of women in rural communities Between the ages of 20 and 40 the mortality rate for rural women is almost as great as that for men, except from 25 to 31 in which period it is actually greater The same is true for negro women from the ages of 10 to 20

SOME EFFECTS OF EPINEPHRIN ON THE DISTRIBUTION OF THE BLOOD

Early in the investigation of the action of extracts of the suprarenal glands and the preeminently active component, epinephrin, produced by them, it became apparent that this substance can exert a pronounced local vasoconstriction The contraction of arterioles which it brings about has rendered it one of the most powerful local styptics, in the same way not only hemorrhage but also inflammation is diminished in mucous membranes to which solutions of epinephrin are applied locally The first classic researches on the effects of suprarenal extracts injected directly into the circulation showed as the invariable outcome a pronounced rise of blood pressure in the arterial system As the pressor response was apparently brought about by diminution in the caliber of the blood vessels, particularly in the abdominal areas, it seemed more than probable that the blood must be driven more effectively into other areas as the result of such special vasoconstriction It is not surprising, therefore, that it was soon concluded that the function of the suprarenals is so to regulate the blood vessel caliber throughout the body that an adequate circulation to the vital tissues can be maintained with a minimal cardiac effort

The physiology of the suprarenals and epinephrin has grown much more complex since these pioneer investigations were completed about twenty years ago The pendulum of opinion respecting the real physiologic significance — rather than the pharmacodynamic potency — of epinephrin has swung back and forth with each new announcement of experiments For a time it appeared as if the actual participation of suprarenal secretion in the regulation of blood distribution was of doubtful occurrence Gradually, however, the discoveries of the relations of epinephrin to the sympathetic nervous system have made it seem most unlikely that in normal life suprarenal secretion should fail to play an important part We know that it acts preeminently on all the functions innervated by the sympathetic system The action of epinephrin on any organ is always the same as the effect produced by excitation of the sympathetic nerve supply to that organ It may vary in different species, just as in some the stimulation of a sympathetic nerve may cause activity, while it causes inhibition in others Furthermore, the action of epinephrin does not seem to be limited solely to these effects on the sympathetic end-organs Lately the possible physiologic importance of suprarenal secretion has been enhanced by the seemingly well founded claims that the stronger emotions lead to discharge of epinephrin into the circulation in more than normal amounts The mobilization of carbohydrates, the efficiency of muscle, the coagulability of the blood, and other functions are said to be affected in ways which make for physiologic preparedness in times of bodily stress

It has been well said that theoretically any hormone might exercise a profound influence on body functions by shifting the circulation in favor of one organ at the expense of another [1] This has led Hoskins and his collaborators[1] at the Northwestern University Medical School, Chicago, to give renewed attention to the possibilities suggested The subject is, of course, not a new one, and the contradictions reported are numerous The data are in many cases fragmentary and incoordinated, having been obtained from observations on isolated organs or localized structures without due regard to the interrelations which may and doubtless do exist between widely different parts of the body The new studies indicate that, in an intact animal, epinephrin in any general sense is neither a vasoconstricting nor a vasodilating agent It is one or the other, depending on what vessels are involved In some cases, as in the lungs, the effect seems to depend on the dosage Epinephrin injected intravenously in the intact animal generally, though not inevitably, causes in all doses a constriction of the limbs, but when the skin of the part is removed, the contraction is converted to expansion There is active vasodilatation in the muscles, whereas the cutaneous vessels experience vasoconstriction Accordingly, the Chicago investigators point out that one cannot generalize to the effect that the splanchnic vessels are constricted while the peripheral vessels are dilated In the peripheral circulation are included not only the skin but also other less extensive structures which respond by constriction, while observations have shown that the intestine is often dilated The effect of epinephrin in such a structure as a limb is a composite one, the limb as a whole either contracting or expanding, depending on whether vasodilatation in the muscle or vasoconstriction in the skin predominates

Considerable emphasis has been placed recently on the possible part played by an outpouring of suprarenal secretion in promoting muscular efficiency Hoskins, Gunning and Berry suggest that the selective vasodilator effect of epinephrin in skeletal muscle probably accounts to a considerable degree for its favorable influence in improving contractile activity as well as hastening recovery from fatigue To these considerations may be added the newer evidence of long claimed possible physiologic interrelationships between the thyroid and suprarenal tissues in the body Augmented thyroid secretion called forth by stimulation appears to sensitize the sympathetic structures so that they respond more effectively to suprarenal secretion[2] The action of thyroid secretion on sympathetic endings is a selective one, for there is no concomitant increase in excitability of the augmentors of the heart Thus the physiology of the endocrine organs has become involved in a maze of complexities through which the light of intelligible interpretation is only beginning here and there to find its way

ACETYLSALICYLIC ACID, NOT ASPIRIN

The Council on Pharmacy and Chemistry publishes a report in this issue giving its reasons for deleting "Aspirin-Bayer" from New and Nonofficial Remedies In order that a standard may be provided, the drug, acetylsalicylic acid, is retained[3] in N N R under its scientific name, acetylsalicylic acid, aspirin appearing as a synonym The attempt on the part of the Bayer Company to perpetuate the monopoly it has had for seventeen years in the United States was briefly discussed editorially in THE JOURNAL, Aug 12, 1916 We quoted from *Printers' Ink*, a magazine devoted to advertising, in part as follows

> "The manufacturers of aspirin are about to launch an extensive advertising campaign to clinch the market as far as possible before the expiration of their patent rights next year The purpose of the campaign is to identify the product *with the trademark of the Bayer Company and to* this extent hamper competition after the expiration of the patent"

It is worth while reminding physicians of the privileges the Bayer Company has enjoyed for so many years, owing largely to our inequitable and crude patent laws, or to their construction First, it should be remembered that practically no other country in the world, not even the original home of the preparation, would grant a patent on either acetylsalicylic acid, the product, or on the process for making that product The United States granted both! As a result, for seventeen years it has been impossible in this country for anybody except the Bayer Company to manufacture or sell acetylsalicylic acid, either under its chemical name or under any other name Neither was it possible for individuals, hospitals or any other institutions to import it, legally, for their own use

Needless to say, the American people have been made to pay exorbitantly for the monopoly our patent office granted this firm Three or four years ago THE JOURNAL, through the American consuls, obtained information regarding the price at which acetylsalicylic acid was sold in foreign countries At that time, acetylsalicylic acid, as "aspirin," was costing American druggists — and of course the American public had to pay still more for it — 43 cents an ounce Just across the border in Canada it sold for one-third the price asked here In some of the foreign countries, acetylsalicylic acid under its scientific name could be purchased by the druggists of those countries at from one-sixth to less than one-tenth the price that it cost American druggists Here are some of the figures

Austria-Hungary	4 cents an ounce
British Isles	6 cents an ounce
Denmark	4 cents an ounce
France	4 cents an ounce
Germany	4 cents an ounce
Holland	4 cents an ounce
Norway	4 cents an ounce
Sweden	4 cents an ounce
United States	43 cents an ounce

Not content with the iron-bound monopoly which it had been granted through our patent laws, the company attempted further to clinch its exclusive rights by giving the preparation a fancy name, "aspirin," and getting a trade-mark on this name The patent on acetylsalicylic acid expires next month (February, 1917) After its expiration the product, and its method of manufacture, become common property American manufacturers will now be able to do what manufacturers in other countries, other than the patentees, have long been doing — make and sell acetylsalicylic acid[4]

Unfortunately, it is extremely improbable that any American manufacturer will market acetylsalicylic acid under the name aspirin, although we believe they would have a legal right to do so The courts have held in related instances that when a patented article has been known during the life of the patent under a trade-marked name, with the expiration of the patent the name as well as the product becomes common property The classical "Singer Sewing Machine" decision and the lanolin case are in point The Bayer Company, through a widespread newspaper advertising campaign, seems to be attempting to perpetuate its seventeen-year monopoly by leading the public to believe that there can be only one brand of genuine acetylsalicylic acid on the market — that made by the Bayer Company

The firm will, of course, continue to manufacture and advertise the product under the name "Aspirin-Bayer," and will probably charge high prices for it, as was the case with phenacetin (acetphenetidin) In any event, physicians hereafter should do what for a long time we have been advising should be done, namely, prescribe the compound under its scientific name, acetylsalicylic acid They should do this if for no other reason than that they would be using the name which carries with it a reminder of the composition of the preparation Of course, for those who have been writing "aspirin" it will be rather difficult to write "acetylsalicylic acid," just as a quarter of a century ago it was difficult for the physician of that day who had been using the copyright name "antifebrin" to write "acet-anilid," a name which nowadays is easy, even for laymen

[2] Levy, R L Studies on the Conditions of Activity in Endocrine Glands IV The Effect of Thyroid Secretion on the Pressor Action of Adrenin Am Jour Physiol 1916 **41**, 492

[3] See page 213, this issue

[4] The Bayer people may try to convey the impression that 'Aspirin is pure and reliable whereas other brands are not. Since acetylsalicylic acid is a definite chemical *compound*, there is no more likelihood of this being sophisticated than there is of quinine being adulterated Furthermore the Council in accepting acetylsalicylic acid for New and Nonofficial Remedies has provided standards of purity which will insure a uniform product The brand of one firm—Powers Weightman Rosengarten Co, of Philadelphia has been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies 1917

GASES, FIRES AND EXPLOSIONS IN MINES

Among the dangers involved in the hazardous occupation of coal mining, those attaching to the gases which may contaminate the air are prominent Up to and including 1912, in 275 coal mine accidents in the United States, in which five or more men were killed, involving a total loss of 6,777 men, 5,111, or about 75 per cent, were killed by gas and coal dust explosions, the next largest category of fatalities including those by mine fires and amounting to somewhat over 15 per cent[1]

Black damp or choke damp, the miner's term for what the chemist discovers to be carbon dioxid, is almost always present in mines in quantities exceeding that in which it appears about us under ordinary conditions of life As carbon dioxid is a product of decomposition, of combustion, and of respiration in man and animals — all factors which play a part in mining operations — the accumulation of this gas in the absence of good ventilation can readily be understood The essential danger of carbon dioxid lies in its possible interference with respiration, on combustion it has at most an antagonistic effect

There are other possible poisonous mine gases, however, such as hydrogen sulphid, or stink damp, and carbon monoxid, the latter of which is highly poisonous even in small quantities For the detection of harmful proportions of the latter, Haldane recommended the use of birds and mice, which succumb to a concentration of carbon monoxid at which men show no symptoms of distress Hydrogen sulphid may be found occasionally as an occluded gas in coal seams In other mines it is usually the product of decomposition of the sulphid-containing pyrites in the presence of moisture When mixed with air it is violently explosive

In mine fire explosions it is undoubtedly methane, hydrogen and carbon monoxid which play a significant role How these gases, dangerous because of their explosibility when mixed with air, arise in mines is not so widely understood Methane, also known as carburetted hydrogen or marsh gas, is a product of decomposition of organic matter and thus can come from pores and pockets in coal, at ordinary temperatures, and can also be produced by heat reactions Hydrogen and carbon monoxid are not found normally in coal mines, hence their presence in the gases of mines which are on fire is due to the destructive distillation of the coal or wood, the action of carbon dioxid and hot coal or wood, and the action of steam on hot carbon The experts of the Bureau of Mines have pointed out in a recent technical paper[2] that in a fire above ground, combustion may be complete because sufficient air can be supplied to the burning material to permit the formation of carbon dioxid and water as the principal products of combustion On the other hand, a mine fire, as a rule, is quickly covered with fallen coal, slate, timber, etc, and the oxygen content of the mine atmosphere is more or less rapidly diminished, and oxygen does not have ready access to the burning fuel As a consequence, combustion soon becomes incomplete, and intermediate products of combustion, such as carbon monoxid, are formed The character and quantity of the gases produced differ according to the stage of the fire, from the time it is first noticed, through the period during which it is being fought, and up to and through the time it is sealed, if sealing becomes necessary The changes which take place may be studied by comparing mine fire combustion processes with changes which coal undergoes, and the gases which are given off when the coal is subjected to different combustion processes above ground Such studies have to do with the destructive distillation of coal in retorts, as in making illuminating gas, the manufacture of coke in coke ovens, the production of producer gas, and the burning of coal in boiler furnaces In mine fires, chemical reactions may occur which are related to the reactions which take place during any of the foregoing well known processes, from that of complete combustion, as in properly fired boiler plants, to destructive distillation, as in gas-house retorts, in which practically no oxygen enters into reaction except that from the coal It is thus that methane, carbon monoxid and hydrogen in particular arise

Usually the methane which makes a mine gaseous is largely responsible for explosions which take place when ventilation is stopped, but the other inflammable gases produced by fire may likewise become largely responsible According to Burrell and Oberfell,[2] methane is the most dangerous gas as regards low limit of explosibility, whereas carbon monoxid and hydrogen are especially dangerous because of their wide explosive ranges In the low-temperature destructive distillation of coal in mine fires, the principal danger is from methane As regards a mine fire which has been burning for some time, it is probable that when the oxygen of the air has been so depleted that products of destructive distillation appear, the embers will have cooled to a point at which the low-temperature products are given off in largest quantity

[1] Kober and Hanson Diseases of Occupation and Vocational Hygiene Philadelphia, 1916 p 619

[2] Burrell G A and Oberfell G G Explosibility of Gases from Mine Fires, Bureau of Mines Technical Paper 134 Washington, D C 1915

According to the government experts, carbon monoxid formed by the reducing action of hot carbon on carbon dioxid is a highly important agent in some mine fire explosions, but it is probable that water gas (carbon monoxid and hydrogen), produced by the action of steam on hot carbon, plays a relatively unimportant role in causing mine fire explosions

THE HEALTH OF MUNITION WORKERS IN RELATION TO THEIR WORKING OUTPUT

The European war has forced attention in an acute way to the problem of the working day, which was recently referred to in The Journal[1] as being primarily a question in physiology It is at first thought almost unbelievable that in a grim struggle in which life is being sacrificed daily in the most reckless and ruthless manner the participants should attempt to make detailed inquiries respecting the relation of conditions of work to the efficiency of the worker Yet this has been done in a variety of ways, for all the combatants realize in this war, as never before, that the dictates of science demand just consideration in a competitive struggle of the most intense description

Overwork which leads to the inefficiency attributable to undue fatigue may be as detrimental as the indifference of the "slacker" who, though fully able to work, fails to meet his working obligations For this reason, evidently, the British minister of munitions has appointed a committee "to consider and advise on questions of industrial fatigue, hours of labor, and other matters affecting the personal health and physical efficiency of workers in munitions factories and workshops" Among the memoranda already published by this committee, a recent memorandum prepared by Dr H M Vernon[2] of the University of Oxford gives instructive statistical information concerning output in relation to hours of work in munition factories under government supervision Many women, for example, were supposed to work more than seventy hours a week in some of the munition plants An actual determination of the output of these employees before and after the reduction of the hours of work under otherwise comparable environmental conditions leaves little doubt that, even aside from any physiologic benefit to the working individual, a great gain results in the fact that as much or even more was actually accomplished in the shorter period Thus, in speaking of one group, Vernon states that it is probable that the sixty hours of work a week were still too many to give the best total output, but they justify the statement that, in order to attain a maximum output, women engaged in moderately heavy manual labor should not work more than sixty hours a week The conclusion derived from observations is that an equally good total output could be maintained if the actual working hours were reduced to fifty-six or less a week Vernon appreciates that it might be thought that the great improvement in hourly output under the shorter hours' regimen was due, partly or wholly, to increased skill of the operatives or improvements in the machinery Neither of these hypotheses can be substantiated

Further proof of the advantage of shorter hours was afforded by the output data of some of the operatives on an earlier occasion One group of seventeen worked only from 51$\frac{8}{10}$ to 62$\frac{6}{10}$ hours a week for five weeks in June and July, and during the last three weeks of this period their hourly output was 18 per cent greater than that of another group of fourteen operatives who were working the usual long hours Subsequently, when the two groups worked the same long hours, their output was identical

The desirability of considering the type of work involved and perhaps even the individual in the regulation of working conditions — a feature emphasized by Lee[3] — is likewise expressed in Vernon's observations He concludes that the hours of labor should be varied between wide limits according to the character of the work performed This obvious fact is not realized by many managers of munitions works, and the tendency is usually toward uniformity of hours for all types of labor and for workers of both sexes The British data suggest that not only are women unsuited to the heavier types of work, but that even when engaged on the moderate and light types they are unable to stand such long hours as the men Several sets of operatives, both male and female, were kept under close observation for many days in order that their powers of application might be investigated Men engaged in boring the powder chamber and in turning and finishing shells were found, almost without exception, to stick to their work with admirable persistence, seldom resting even for a minute On the other hand, women engaged in turning fuse bodies rested for various periods which in the aggregate amounted to one and one-half hours out of the twelve-hour day, and over an hour out of the ten-hour day, in addition to the hour or so of compulsory rest required for attention to their lathes at the hands of the tool setters About half an hour of the voluntary rest pauses occurred at the beginning and close of work, but much of the remaining hour or half hour was probably due, not to idleness on the part of the women, but to fatigue, and to an instinctive knowledge that short rest pauses helped to prevent undue fatigue

---

[1] Physiologic Aspects of the Working Day Problem, editorial The Journal A M A Jan 13 1917 p 122

[2] Vernon H M Statistical Information Concerning Output in Relation to Hours of Work Health of Munition Workers Committee, Memorandum 12, 1916

[3] Lee F S Is the Eight Hour Working Day Rational? Science, Nov 24 1916 p 727

In considering the specific facts related in the British memorandum, it must be remembered that the work is being conducted under great stress Realizing this, Vernon says that the hours still in force necessarily impose a great strain on the operatives, and there can be no doubt that in many instances the strain is too great to be borne, and that the operatives are compelled to drop out altogether That is to say, the data quoted relate to the fittest who were strong enough to survive in the struggle, and not to the general mass of workers of all classes who tried to do munition work It is almost impossible to discover the extent of this weeding out, but it is inevitably considerable Hence the best hours of work, suited for peace times, are in every case considerably shorter than those mentioned, though the principle of graduating the number of hours of labor to the type of work performed still holds with undiminished force

Current Comment

CREATINURIA IN CHILDHOOD

Although creatinuria in adults is commonly believed to belong essentially to the pathology of metabolism, the excretion of creatin along with creatinin in the urine of children has been accepted as a phenomenon of normal character ever since it was carefully studied by Rose [1] Creatin is usually excreted by children until the age of puberty It forms a fairly large component of the total creatin plus creatinin present in the urine at this early period of life No satisfactory explanation for this peculiar difference between the metabolism of the young and the adult has been given until recently, when Powis and Raper[2] made observations on the incidence of creatinuria which may help to throw light on the problem They found in a study of the diurnal and nocturnal variations in the excretion of creatinin and creatin in children that the rate of creatinin output is slightly less during the night than during the day More striking is the fact that the rate of creatin excretion is highest during the morning, less during the latter part of the daytime, and very small at night The chief factor in the output of creatin appears to be the state of rest of the skeletal muscles associated with the temporary cessation of voluntary control which occurs during sleep Powis and Raper conclude that the results so far obtained are most simply explained by assuming that creatinuria in children is due to the immaturity of the muscles Creatin is not entirely an index of endogenous metabolism in the way that creatinin is, because the two do not show parallel variations This may be due to the fact that creatin is utilizable, whereas creatinin is not The production of creatin at night is probably lower than during the day, and anabolic processes at rest, by utilizing or destroying part of it, cause a further diminution in the amount excreted Sleep is apparently not the only factor involved, since creatin excretion during the afternoon is less than during the morning In a case of amyotonia congenita studied by Powis and Raper[2] at the University of Leeds, the excretion of creatinin per kilogram of body weight was much lower, and that of creatin much higher, than for a normal child of the same age Morse[3] has found a high creatin content in the urine of children with diseases involving atrophy These involved less extreme cases of muscular immaturity than amyotonia congenita, in which the muscles are soft, toneless and underdeveloped Putting the known facts together with these observations, the British investigators conclude that the fully matured muscle produces only creatinin, and no creatin, or only such small amounts that utilization processes prevent their coming to excretion As the child develops, the creatinin coefficient gradually increases, and the creatin diminishes until it finally disappears This hypothesis will doubtless be tested further by students of metabolism in adolescence

TRAFFIC ACCIDENTS

At least 60 per cent of all accidents are street and traffic accidents Figures just announced by the Bureau of Records of the Department of Health of the City of New York show that there were 18 per cent more deaths from accident during the first eleven months of 1916 than during an equal period in 1915 The experience of New York is not unique in regard to street accidents The figures for Chicago and other large cities show the same alarming increase The "safety first" campaign has not yielded the same satisfactory results in street accidents that it has in industrial establishments and for railroads The reason is plain cities are not managed on the business principles industrial establishments employ Perhaps another factor is that "safety first" signs have become so common that pedestrians no longer pay attention to them When cities study these problems in the same scientific manner that private corporations study them, and apply the remedy indicated, the number of preventable traffic accidents will decrease

A MEDICAL METAPHOR

Stump speakers, Chautauqua lecturers and graduation orators utilize the classics, poetry and romance to add polish to their effusions, they seldom go to the sciences, and least of all to medicine, for this purpose, as did Congressman Bennett of New York, who, recently, in a discussion of a proposed rule, "brought down the House' with the following

> What does this rule do? In the first place, it performs a cesarean operation on the Committee on Interstate and Foreign Commerce, and takes from it a resolution that it has a perfect right to show its parturitive ability by itself delivering

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH ETC)

ALABAMA

Unified Health System for Birmingham—After a conference between Dr Francis E Harrington the new health officer of Jefferson County, and Dr Cecil D Gaston city health officer of Birmingham, it was announced that Dr Gaston would continue to act as city health officer According to the plans for a unified health system prepared by Surg Carroll Fox, U S P H S, the share of expense of the county for the new system will be about $30,000 'The unified plan provides that the health supervision of the Birmingham public schools now handled by the board of education, shall be placed under the supervision of the county health officer

ARKANSAS

Birth and Death Registration—The Supreme Court of Arkansas has decided that local registrars of births and deaths appointed by the state registrar of vital statistics are state officers and cannot be paid by the counties In that respect the law recently passed providing for the appointment of such local registrars is held to be unconstitutional The opinion is published in full in *Public Health Reports*, Jan 5, 1917

CALIFORNIA

State Society Meeting—The Medical Society of the State of California will hold its next annual meeting at the Hotel del Coronado, San Diego, April 17

Psychopathic Hospital Needed—The California Society for Mental Hygiene recommends a law providing $500,000 for a psychopathic hospital to be conducted as a unit of the Affiliated Colleges under the management of the University of California The association also endorses the establishment of a state colony in southern California for mental defectives, to cost $250 000 The following officers were elected president Dr George E Ebright, San Francisco, vice presidents, Drs Robert L Richards, Talmadge Lillian Martin and Fred W Hatch Sacramento, secretary, Miss Julia Green, and treasurer, Mr Knox Maddox

Personal—Dr Harry J Pittock Pasadena, resident physician of the LaVina Sanatorium, has accepted a position as assistant to Dr Floyd L R Burks, Fresno——Dr George B Somers has been reappointed a member of the board of health of San Francisco——Dr George F Pache Angels Camp is under treatment at St Joseph s Hospital Stockton for septicemia——Drs Howard Wright, San Francisco and Fred Cozelman Los Angeles have been appointed to the medical staff of the Stockton State Hospital——Dr Edward H Julien San Francisco was seriously injured in an automobile collision, December 28——Dr George H Derrick Oakland was held up, December 23, and robbed of his watch fob and money——Dr Judson Liftchild Ukiah has resigned as superintendent of the Mendocino County Farm and Hospital after ten years service

DISTRICT OF COLUMBIA

Education of Tuberculous Children—The board of education has appealed to the public for $1 000 for fifty-nine tuberculous children recently excluded from school Buildings and teachers are available, but there is no fund for transportation blankets clothing or food It is expected that Congress at the present session will make provision for the education of these children after the present school year

IDAHO

Personal—Drs D E Everette and Susie V Standard Burns Ore have moved to Nampa——Dr Ralph Falk Boise, has resigned as secretary of the state board of health——Dr Ellis Kackley Soda Springs, has succeeded Dr Oscar B Steely, Boise, as a member of the state board of health

ILLINOIS

State Hospitals Society to Meet.—A meeting of the Illinois State Hospitals Medical Society will be held January 25 and 26 at the Chicago State Hospital Dunning Ill.

Sanatorium Directors Named—Rev John P Quinn, Ottawa, Mrs Virginia LeRoy, Streator, and Dr Kimball W Leland, Utica, have been appointed the first board of directors for LaSalle County Tuberculosis Sanatorium, and have been given authority to select the site for the building, and to determine the kind of structure to be erected, the plans to be subject to the approval of the state board of health

Health Consolidation in Illinois—In the interest of economy and better administration Governor Lowden has adopted a general policy for the reorganization of the executive department of the state government and the consolidation of as many departments and bureaus as possible As a part of this policy, plans are being considered for the assembling in a department of health of the present state board of health, the state board of pharmacy, the state board of dental examiners, the nurses examining board, the new optometry board and others A bill providing for a department of health with a commissioner at the head will probably be introduced early in the present session of the legislature.

Chicago

Women Hear About Health Insurance—The Medical Women s Club of Chicago gave a dinner and reception at the college club rooms of the Chicago College Club, January 10 at which Dr William A Evans spoke on "Health Insurance'

Annual Meeting of Visiting Nurse Association—At the twenty-seventh annual meeting of the Visiting Nurse Association of Chicago, held at the Blackstone Hotel January 17, Dr Hugh T Patrick, on behalf of the committee on the after-care of infantile paralysis delivered the principal address Reports were made by the various committees, and officers and directors for 1917 were elected

INDIANA

New Officers—At the annual meeting of the Fort Wayne Medical Society, December 5 Dr Charles G Beall was elected president, Dr Allen Hamilton vice president, Dr Miles F Porter, Jr, secretary, and Dr Elmer E Morgan, treasurer

Care of Mental Defectives—The board of state charities in its biennial report to the legislature, recommends adequate care and prevention for mental defectives The five hospitals for the insane in Indiana are now so crowded that it is impossible to classify the patients Instead of enlargement of existing hospitals or the building of new ones, the board recommends the purchase of farms a short distance from the hospital, yet near enough to be under its supervision A beginning has been made in the purchase of a colony farm near the Eastern State Hospital, Richmond

Personal—Dr Loren A Hyde Indianapolis, has succeeded Dr Benjamin S Potter as superintendent of the Marion County Hospital for Incurable Insane at Julietta——Dr Brown S McClintic, Peru, after three years' service with the Russian army, is on his way home——Dr Paul F Martin, Indianapolis, who went abroad last May under the auspices of the American Medical Relief Expeditionary Association, is now in charge of 2 000 beds in the Pardubitz Hospital Austria, which has a capacity for 10 000 patients——Dr Noah D Berry, Muncie was knocked down by an automobile recently and suffered painful injuries——Dr Arthur L Oilar who has been ill with appendicitis in the Methodist Hospital, Indianapolis, is reported to be improving——Dr E Trent Stout Upland, has started for the border in command of an ambulance company

IOWA

Personal—Dr Ella Blackburn, assistant physician at the State Hospital, Mount Pleasant has accepted a position as assistant physician at the Kenilworth Sanitarium, Kenilworth Ill to succeed Dr Margaret S Grant who has been appointed pathologist at the Lutheran Hospital, Fort Wayne, Ind——Dr Charles E Nelson Centerville, suffered severe injuries in a collision between streets cars in Burlington, December 26——Dr Thaddeus C Cooper, Ogden will leave in a short time for six months' work with the English forces on the western front——Dr Adolph M Evetz, Carroll was painfully injured in a runaway accident, December 22

State Supply of Antitoxins—The state board of health has contracted for a year's supply of antitoxin which will be distributed from 250 stations The board expects to increase the number of stations to 300 The state contracts for the antitoxin at less than one fourth the rate to the drug trade and then retails it at cost. The new prices for diphtheria antitoxin are 1 000 unit package, 50 cents, 3 000 units, $1.25, 5,000 units, $1 80, 10,000 units, $3 35 Tetanus antitoxin will be sold at the following prices 1,500 units, $1 67, 3,000 units, $2 87, 5,000 units, $4 Typhoid vaccine in the three-ampule package will sell for 28 cents These prices are lower than last year Smallpox vaccine has also been reduced in price

KENTUCKY

License Revoked—It is reported that at a recent meeting the State Board of Health of Kentucky revoked the license of Dr John Karagiozian of Louisville on the ground of his dispersing narcotic drugs for purposes other than their legitimate use

Personal—Drs Lewis S McMurtry, Hugh N Leavell and Clarence H Harris have been appointed, by the state board of health, members of the Jefferson County Board of Health for two years——Dr Philip E Blackerby, Erlanger, has been appointed registrar of vital statistics by the state board of health, to succeed Dr W Lucien Heizer, Bowling Green, recently appointed secretary of the state tuberculosis commission

MARYLAND

New Superintendent for Sydenham Hospital—Dr Harry H Johnson, Baltimore was appointed superintendent of the Sydenham Hospital, January 2, succeeding Dr John F Hogan, Baltimore, appointed second assistant commissioner of health

Rare Books Presented to Johns Hopkins Library—A number of valuable and rare old medical books the collection of which covered thirty years, have been given to the Johns Hopkins University library by Dr Henry J Berkley, clinical professor of psychiatry in the Johns Hopkins Medical School

Personal—Dr John T O'Mara, Baltimore, has been appointed physician to St Mary's Industrial School, to fill the vacancy caused by the recent death of Dr Alexander H Saxton, Baltimore——Dr Archibald C Harrison is a patient at St Joseph's Hospital where he recently underwent an operation for appendicitis——Dr Joseph I Lawrence, formerly associated with the American Ambulance in Paris, read a paper before the Baltimore Medical Society, January 5 on The Method of Treating Wounds as Practiced by Carrel"

Annual Meeting of the Eudowood Board—Dr Henry Barton Jacobs, Baltimore, president of the board of directors of Eudowood Sanitarium, points out in his report the need of a nurses' home and advantages of the development of the farm colony into an industrial colony in which shops could be established and men could pursue their trades while regaining their health——Dr Martin F Sloan, Towson, the superintendent, stated that 302 patients had been treated, 200 of whom had been discharged Of these, seventy-nine were able to return to their former work

Hunterian Laboratory Opened—The Hunterian Laboratory of Johns Hopkins Medical School, the dream of the foremost physicians and surgeons of Johns Hopkins Hospital years ago, has been completed and is now formally opened The building cost about $115,000 Its erection was made possible through the munificence of the Rockefeller Foundation The scientific equipment alone cost many thousands of dollars The purpose of the laboratory is to facilitate the work of the men engaged in the highest form of research work Tunnels connect the laboratory with the medical school and the physiologic building On the first floor are the medical library and the department of art as applied to medicine Work at the laboratory is directed by a committee of professors and instructors of the medical school Dr Milton C Winternitz is chairman of the committee, and has a laboratory on the fourth floor The second floor has been leased to the Carnegie Embryological Institute The third floor will be devoted to work in clinical medicine and children's diseases The pathologic department will be located on the fourth floor

Commission to Study Feebleminded—After a conference with Dr Arthur P Herring, Baltimore, secretary of the State Lunacy Commission, the governor has announced that he will appoint a commission to study causes of mental defectiveness and to suggest preventive methods The thirty-first annual report of the lunacy commission shows that there are at present 5,065 patients in all the institutions in Maryland, public and private The total number under treatment during the year was 7,048, and 2,215 patients were admitted to the institutions during 1916 Of this number about 25 per cent were discharged as recovered The ratio of the insane to the population in Maryland is 1 270 The State Lunacy Commission asks that the investigating commission be composed of two members of the last legislature, one or more of the superintendents of the state hospitals for the insane and feebleminded, a representative of the state and city public school boards, a representative of the State Board of Penal Control, the secretary of the lunacy commission, the secretary of the state board of health, and one or more persons who have given special attention to the subject in some of its phases The governor also announced his intention of later appointing a commission to study and report on the tuberculosis situation in Maryland

MICHIGAN

Physician Fined—Dr Lemen L Harrison, Niles, charged with neglecting to notify the health authorities of a case of scarlet fever, pleaded guilty and was fined $10 and costs

Personal—A farewell reception was given in honor of Dr Gale W Huber, Detroit, city physician at the Receiving Hospital, December 4——Dr Robert A McGregor, Jackson, has been appointed state prison physician——Dr William H Cressy, who has been serving in the Russian Medical Corps, is home on leave and is visiting in Grand Rapids——Dr Henry T Sethney, Menominee, is ill with diphtheria

MISSOURI

Personal—Dr William E Minor, Kansas City, has recovered from an operation for appendicitis——Dr Eugene H Bullock, Edina, has been selected as superintendent of State Hospital No 2, St Joseph, succeeding Dr William L Whittington——Dr Hasbrouck Delamater, Kansas City has been appointed full time health officer of St Joseph——Dr Austin B Allen, Marysville, has retired after nearly forty years of practice He will spend several months in southern California

St Louis

Gifts to Society—The heirs of Dr Charles H Klie have presented a bust of Aesculapius and a number of volumes to the library of the St. Louis Medical Society——Vice President William H Stauffer has presented a clock to the society

The Workman's Compensation Law—The meeting of the St Louis Medical Society, January 13, was devoted to the proposed Workman's Compensation Law for Missouri, which comes before the legislature for action this month or February The subject was presented by Dr Malcolm A Bliss

Personal—Dr Hugo Summa will spend several months in California——Dr Malvern B Clopton, associate in surgery in Washington University Medical School, who has been on duty with the American Ambulance in Paris, delivered an illustrated lecture recently on "American Ambulance Work in Paris" at the annual meeting of the Pilgrims' Congregational Church Brotherhood——Dr W H Wiedemann will deliver a lecture before the St Louis Academy of Medicine, January 29, on "Chemistry of High Explosives and Poisonous Gases as Used in the European War"——Drs Walter C G Kirchner Lux H Bock, Benjamin W N Klippel and Allan A Gilbert have been appointed to the St Louis Unit of the American Physicians' Expeditions Committee

NEW JERSEY

Personal—Dr Albert Pittis, Plainfield is reported to be seriously ill with septicemia, due to an operation wound, in the Huhlenberg Hospital, Plainfield——Dr Millard Knowlton, health expert and publicity agent for the state department of health, Trenton, has resigned——Dr Charles S Braddock, Jr, Haddonfield, is reported seriously ill in New York as the result of a cerebral hemorrhage——Howard E Winter, Plainfield, has been appointed a member of the state department of health, to succeed the late Dr John R Everett, Trenton

NEW YORK

Hospitals for Insane Overcrowded—The State Hospital Commission reports that $2,000,000 a year for the next five years must be spent to provide for the insane in New York There are 34,000 insane persons in the state hospitals, which have a normal capacity of 28,000 The commission favors the construction of a new hospital at Mohansic and of new buildings at Marcy, near Utica, where 1,500 of the insane of New York City could be sent

New York City

Health Department to Furnish Pneumonia Serum—The city department of health announces that it will supply for the treatment of lobar pneumonia a serum perfected by the Rockefeller Institute of Medical Research

Health Department Will Examine Cancer Tissue—The budget of the department of health for 1917 provides for a pathologist who will examine tissue for cancer diagnosis The work will be conducted under the bureau of laboratories as soon as the details can be arranged

Staffs of City Hospitals Dine—The medical staffs of the nine hospitals of the department of charities, about 450 physicians, dined recently at the Hotel Astor Commissioner John A Kingsbury was toastmaster Among the speakers were Mayor Mitchell, Comptroller Prendergast, and Drs James J Walsh and Orrin S Wightman This is the first time that all the attending and house physicians of the city hospitals have been called together

Report of Charity Organization Society—The report for the fiscal year, ending Sept 30, 1916, shows that while practically the same number of persons received aid as during the years of 1912 and 1913, the years immediately preceding the period of widespread unemployment, there has been an increase in the amount of illness encountered In 3,000 families 2,016 cases of illness were found, including tuberculosis, respiratory and digestive diseases, rheumatism and paralysis In 198 instances there were mental defects, and in about 20 per cent of the cases alcoholism and the use of drugs were complicating problems

Personal—Dr Hermann M Biggs, state commissioner of health, has been granted an indefinite leave of absence on the urgent request of the Rockefeller Foundation, that he may go to France to study the tuberculosis problem there and organize measures to combat the spread of the disease in that country Dr Biggs is accompanied by Dr Alphonse R Dochez of the Rockefeller Institute——During the absence of Dr Biggs, Dr Linsly R Williams, deputy health commissioner, will be the acting commissioner——Dr Alfred E Shipley, Brooklyn, has been appointed secretary of the board of health, to succeed Eugene W Sheffer, who was retired, January 1, after more than twenty years of service——Dr John S Billings, Jr, deputy commissioner of health, and director of the bureau of preventable diseases, has resigned, to take effect May 1 Dr Billings has been in the service of the city for more than twenty years——Dr Woods Hutchinson sailed on the *St Paul* for Liverpool, January 13

OHIO

Hospital Closed—The Stamm Hospital, Fremont, was closed December 30, for the first time in sixteen years This leaves Fremont without a hospital of any kind

Hospital Corpsman Dies—J S Clifton, a former medical student in the Ohio State University, and a member of Ohio Field Hospital No 2, died from pneumonia at the base hospital, El Paso Texas, December 21

State Board Meeting—At the annual meeting of the State Medical Board in Columbus, January 2, Dr John H J Upham, Columbus, was elected president, Dr John K Scudder, Cincinnati, vice president, Dr George H Matson, Columbus, secretary (reelected), and Dr Sylvester M Sherman Columbus, treasurer (reelected) Eugene C Waters, Chillicothe, was appointed on the osteopathic committee, succeeding E R Booth, Cincinnati

Personal—Dr David E Sheehan, director of safety of Cuyahoga Falls, has resigned to accept the superintendency of a clinic in the dental school of the Western Reserve University, Cleveland——Physicians of Nelsonville have presented Dr Isaac P Primrose with a handsome leather chair, in recognition of the completion of fifty-eight years of practice in Nelsonville and vicinity——Dr John E Monger, Greenville has been appointed state registrar of vital statistics——Dr Martin Stamm Fremont, will sail for South America, January 28

Cincinnati

Appropriation for Sanatorium—The county commissioners of Hamilton County have appropriated $25 000 for the Cincinnati Tuberculosis Sanatorium

Medical Reserve Corps Division Organized—The Cincinnati Section of the Association of the Medical Reserve Corps U S Army, organized, December 7, and elected Lieut Robert D Maddox president, Lieut Goodrich R Rhodes, vice president, and Lieut Elmer A Klein secretary-treasurer

Personal—Dr Wade W Oliver, a member of the staff of physicians appointed by the Rockefeller Foundation to study disease in South America, who was taken ill with appendicitis while in Buenos Aires is making a satisfactory recovery after an operation——Dr Ernest Zueblin, professor of medicine in the University of Maryland, Baltimore, has accepted a position on the faculty of the Medical Department of the University of Cincinnati, and will be director of the tuberculosis service at the Public Hospital——Drs Charles A L Reed and John E Greiwe have resigned as members of the staff of the Cincinnati General Hospital——Dr Edward F Nippert, of the house staff of the Cincinnati General Hospital will sail for Germany this month for service in a hospital unit——Dr Gustav A Hinnen has resigned as a member of the junior staff of the otologic service at the Cincinnati General Hospital

PENNSYLVANIA

Record of Pennsylvania Railroad—On the Pennsylvania lines east of Pittsburgh 196,294 146 passengers were carried last year without a fatality, and in the last four years 616,626,957 persons have been transported without loss of a life On the entire system of the Pennsylvania Railroad, east and west of Pittsburgh, three years have passed without the loss of a passenger's life, and in this period 553,890,063 persons have been carried a total of 15,000,000,000 miles by 9,000,000 trains over 12,000 miles of railroad and 27,000 miles of trackage

Philadelphia

Estimates Invited for Institution for Feebleminded—The Department of Health and Charities has invited estimates on four dormitories and connection corridors at the Philadelphia Institute for Feebleminded, Byberry Farms

Council Reconsiders Omission of Money for Nurses—An ordinance was introduced, January 4, in the common council to provide $25,000 to reemploy the nurses who were engaged until about a week ago in caring for convalescents from infantile paralysis, but who were dropped for lack of funds to pay them

Personal—Dr W Wayne Babcock was operated on for removal of the appendix, December 15, at the Samaritan Hospital——Dr John K Mitchell, who has been confined to his home with heart trouble, has greatly improved——Dr Richard H Harte addressed the Philadelphia Association Medical Reserve Corps, U S Army, January 19, on the "American Red Cross Base Hospital"

Banquet for Dr Jackson—The Philadelphia Laryngological Society will tender a dinner, January 23, to Dr Chevalier Jackson, Pittsburgh, recently called to the chair of laryngology of the Jefferson Medical College to succeed the late Dr D Braden Kyle Dr Jacob Solis-Cohen will make the address of welcome Dr J Chalmers DaCosta will represent Jefferson Medical College Dr Edward Martin, the University of Pennsylvania, and Dr Judson Daland, the Medico-Chirurgical College Dr Hobart A Hare will act as toastmaster

SOUTH CAROLINA

Course in Public Health—The Medical College of the State of South Carolina has provided a course of lectures in public health The first lecture in the course was delivered by State Health Officer James A Hayne Other lectures will be given during the season

Personal—Dr Luther A Riser Columbia, has been appointed assistant in the field work of the United States Public Health Service——Drs Charles W Kollock, A Johnston, Buist, and Ernest C Baynard, Charleston have been elected members of the Roper Hospital Fund Commission

New Officers—The South Carolina Medical Society, Charleston, December 27 president, Dr Lane Mullally, vice president, Dr Edward Rutledge, secretary, Dr Henry P Wagener and treasurer, Dr Daniel L Maguire——Sumter County Medical Association December 26, president, Dr Thomas R Littlejohn, vice president, Dr Archie China, and secretary-treasurer, Dr Marvin L Parler——Spartanburg County Medical Association at Spartanburg, December 29 president, Dr James E Edwards, vice president, Dr W Boykin Lyles, secretary, Dr L Rosa H Gantt, and treasurer, Dr Walter B Lancaster

TENNESSEE

New Officers—At the annual meeting of the Memphis and Shelby Counties Medical Society, December 19 Dr William Britt Burns was elected president, Dr William F Clary, vice president, Dr Robert H Miller, secretary, and Dr W Battle Malone, censor, all of Memphis

Personal—Dr W Scott Farmer, Cookville, has been elected superintendent of the Central Hospital for the Insane, near

Nashville, succeeding Dr Albert E Douglas, Nashville, resigned ——Dr Harold S Hulbert, Ann Arbor, has been selected by the state board of control to complete the survey of the Tennessee hospitals for the insane, and also a county survey ——Dr Bryce W Fontaine, Memphis, has been appointed representative of the Memphis and Shelby Counties Medical Society on the directorate of the Memphis Antituberculosis Society

WASHINGTON

State Board Election—At the annual meeting of the State Board of Medical Examiners, held in Spokane, January 2 Dr Royal A Gove Tacoma, was elected president, Dr Daniel M Stone, Seattle, vice president, Dr Conrad N Suttner, Walla Walla, secretary, and H R Morse, Wenatchee, treasurer

Combination of Boards Recommended—State Auditor Clausen, in his annual report, recommends that the medical board, pharmacists board, embalming examiners board, dental board optometry board hotel inspectors board and barber examining board be consolidated under the state board of health in order to obtain greater efficiency, and to decrease the cost of operation

WISCONSIN

Group Practice—Six physicians of Marshfield have organized the Marshfield Clinic

Sanatorium for La Crosse—The County Board of Supervisors voted, December 28, to establish a sanatorium for the treatment of tuberculosis, to cost $50 000

Milwaukee Leper—The United States Public Health Service has notified the health authorities in Milwaukee that the government will not be responsible for the care of the Greek leper found in that city

Children's Hospital—The board of directors and the medical staff of the Milwaukee Children's Hospital are considering plans for the new hospital made possible by the gift of $150,000 by Mr Ferdinand Schlesinger, conditioned on the raising of an equal sum for the endowment of the institute

Contagious Diseases—On account of the spread of scarlet fever and diphtheria, the board of health at Stevens Point on December 28 closed all grade and parochial schools, the model school of the State Normal School and all junior Sunday schools Children and young people were warned away from the moving pictures shows, stores and other places of public gathering

New State Laboratory Opened—The second state cooperative laboratory, organized by joint action of the municipality and the state board of health, has been opened in St Mary s Hospital, Fond du Lac in charge of Dr Frederick M Harris La Crosse, as director The state board of health grants state aid of $500 a year to the laboratory, the city defraying the remainder of the director's salary and the expense of housing and upkeep

Personal—Dr John W Coon, Waukesha, has purchased a controlling interest in the River Pines Sanatorium, Stevens Point, and will assume immediate charge ——Dr B L Williams has succeeded Dr Frank Brockway, Oshkosh, as superintendent of the Wisconsin Tuberculosis Sanatorium, Wales ——Dr Jacob Lang was the guest of honor of the Milwaukee Medical Society, December 14, when the semicentenary of his entrance into practice in Milwaukee was celebrated ——Dr William E Buschman, Milwaukee, is said to be seriously ill with cerebral hemorrhage ——Dr John R McDill, Milwaukee, chief surgeon of the American Physicians' Expedition and on duty at Grandez, West Prussia, has been appointed inspector of fortress hospitals ——Dr Paul Withington, Madison, has been appointed coach of the Wisconsin University football team

CANADA

Health Officers to Meet—The Ontario Health Officers' Association will hold its annual meeting in Toronto, May 29 and 30

Personal—Capt E Stanley Ryerson who has been with the University of Toronto Base Hospital at Saloniki, has returned to Toronto on a short leave of absence ——Col James A Roberts of the University of Toronto Base Hospital has arrived in England from Saloniki It is reported that the University Hospital will probably be withdrawn from Saloniki, as many of the men have suffered severely in health ——Dr Walter W Chipman, Montreal has been appointed medical inspector of military hospitals throughout Canada

Hospital News—Canadian soldiers are now being sent home from England for active hospital treatment, and not merely for convalescent hospital treatment, thus necessitating large additional accommodation ——At Montreal eighty beds are being provided in the Royal Victoria Hospital, 300 in the Grey Nunnery, at Ottawa, eighty beds in St Luke's Hospital, at Kingston, 600 in the Queen's University Building, at Winnipeg, 100 in the General Hospital, at Edmonton, 150 in Strathcona Hospital, and at Vancouver, 300 in the General Hospital ——For convalescent Canadian soldiers, the hospital commission has secured the Loyola Building in Montreal, which will accommodate 200 patients, the Rest Haven Building, Vancouver Island, B C, 200, the Spadina at Toronto, 230, and the Ontario Military Hospital at Coburg, for 150 neurasthenic patients ——The Central Prison at Guelph, Ont, is to provide accommodation for 500 returned soldiers ——The Canadian accommodation for military tuberculous patients is now as follows Kingston 175, Hamilton, 175, London, 110, Frank, Alberta, 60, Kitchener Ont, 30, and Sunny View, Kamloops, B C, 20, New buildings are being provided at Kingston, Hamilton and London, Ont ——Surgeon General Kendall of the Gravenhurst Sanatorium has been put in charge of training physical instructors in Toronto so that every convalescent hospital in Canada will have a physical instructor ——A handbook for soldiers suffering from tuberculosis has been issued by the Canadian Military Hospitals Commission It was written by Lieut John R Byers, M D, in charge of the two sanatoriums at Ste Agathe Que *A copy has been sent to every Canadian soldier in Canada* and overseas ——Mr S A Armstrong, deputy provincial secretary for Ontario has been placed in charge of organization and supervision of hospitals under the Canadian Hospitals Commission

GENERAL

Bequests and Donations—The following bequests and donations have recently been announced

Episcopal Hospital Philadelphia $500 Presbyterian Hospital $2 000 and Methodist Hospital $1,000 by the will of Martha L Binder, Philadelphia

Chester Hospital, Viscose Company of Marcus Hook and its employees a contribution of $1 523 65

Homeopathic Hospital, Chester County, a donation of $20 000 from Mr Pierre S DuPont contingent on the raising of an additional $30 000

German Hospital Philadelphia $5 000 by the will of Otto C Wolf

Medical Education in Chicago—The subscription of the $5 300 000 for the development of higher medical education in Chicago, in accordance with the plans announced in The Journal, Nov 18, 1916 is nearing completion The following list shows the contributions so far made for this purpose

General Education Board	$1 000 000
Rockefeller Foundation	1 000 000
Mr and Mrs Julius Rosenwald	500 000
F H Rawson	300 000
Martin Ryerson	250 000
J Ogden Armour	200 000
Billings family for Albert M Billings Memorial Hospital (C K G Billings Albert Billings Ruddock Charles H Ruddock and Dr Frank Billings)	1 000 000
Mrs Gustavus Swift	100 000
Charles Swift	100 000
Dr Norman Bridge	100 000
Three anonymous contributions of $100 000 each and one of $50 000	350 000
Mrs Edward Morris	50 000
A D Thompson, Duluth (James Nevins Hyde Memorial)	25 000
Charles I Grey	20 000
Robert L Scott	5,000

This makes a total of $5 000 000, and leaves $300 000 to be raised The Albert M Billings Hospital will be built on the Midway, and will consist of a $1,000,000 building containing 250 beds which will be utilized for teaching and clinical study It will have an endowment of $3 000 000 The entire teaching force of the undergraduate medical school on the Midway *including the clinical* departments of the Billings Memorial Hospital, will be full time salaried men The F H Rawson gift of $300,000 will be used to erect a laboratory building for the graduate school, on the site of the present Rush Medical College Building In the graduate school, the heads of the departments of medicine, surgery and obstetrics and all the laboratory men will be whole time salaried instructors Promises already made practically complete the $8,000 000 required The organization and administrative details will be worked out later

Martin I Wilbert—An Appreciation—The following has been unanimously adopted by the members of the Council on Pharmacy and Chemistry W A Puckner, Secretary

The death of Martin Inventius Wilbert, a member of the Council on Pharmacy and Chemistry of the American Medical

Association since its organization, removes one of its most able and loyal members He was possessed of an intellectuality and a manhood which commanded the attention and respect of the members of both the medical and the pharmaceutical professions He was fearless, honest and unselfish He was uncompromising in his denunciation of the evils which beset the practice of medicine and pharmacy, but was never ungracious either with his pen or in his speech If after due deliberation he was sure that a definite policy should be promulgated to improve the conditions of these professions he proclaimed his view and conducted a campaign that inevitably received the support and recognition of those best informed He gave a life of service with never a thought of reward and earned every honor which was bestowed on him His knowledge of pharmacy was such that he could have obtained prominence in the manufacturing field and with it would have come a large measure of financial reward But he chose to devote his thoughts and energies to the general good rather than to his own profit His influence on medicine and pharmacy was unique The forcefulness of his personality was equaled only by his modesty and sincerity His greatest work—one which will be cherished as a part of the history of the American Medical Association—was his devotion to the aims and objects of the Council on Pharmacy and Chemistry and his unselfish and indefatigable labors in its behalf

We, the members of the Council on Pharmacy and Chemistry of the American Medical Association, mourn the loss of one of our most useful associates, and one whose life may be held up to the younger generation of pharmacists as an example of unselfishness and devotion to high ideals

FOREIGN

Poliomyelitis in South America—Advices from Montevideo, Uruguay, state that twenty-four cases of infantile paralysis have been reported in that city

Medical Society for Mechanotherapy—At Berlin has been recently founded the Aerztliche Gesellschaft fur Mechanotherapie The board consists of Schutz, Berlin, Hasebroek, Hamburg, Egloff Stuttgart, Hirsch, Salzschlirf, Lubinus, Kiel, and Jacob, Posen

Typhoid at Lisbon—There has been a sudden outbreak of typhoid at Lisbon, 236 patients having been admitted to hospitals in two weeks It is estimated that there were 639 cases throughout the city In the 1912 epidemic there were 1,023 patients admitted to the hospitals in one week In that epidemic the mortality was 9 7 per cent The drinking water is probably responsible for the epidemic

Pasteur Institute at Florence, Italy—The report of the P Grocco Institute for the four years ending with 1915 shows that 1,947 persons applied for treatment and that 1,336 were given the antirabic course The highest number of applicants in any month was in April, with 132, and the lowest in February, with sixty eight Of those given treatment ninety-seven had been bitten by cats, 1,109 by dogs and twenty-three by pigs The total mortality was 0 48 per cent, and since the foundation of the institute, 0 29 per cent The reduced mortality for this entire period has been 0 092 per cent

Prizes Awarded by the Academy of Medicine at Paris—The Academie de Medecine had thirty-seven prizes to distribute at its annual meeting in December but more than one third could not be awarded, as no suitable articles had been received in competition One prize was given to J Glover of Paris for his research on what he calls the *voix solidienne* in contrast to the *voix aérienne* By this he means the vibrations which the different tissues at the moment of the emission of the voice, conduct to the entire surface of the body, even to the hands and feet He has devised means to collect transmit, measure and record these vibrations He includes respiratory and cardiovascular movements as well as vocal vibrations The prize for historical research was awarded to E Wickersheimer, who has been editing the annual reports of the medical department of the University of Paris The faculte de medecine dates from the thirteenth century, its first known records bear the date of 1267 The earliest reports are lost, but from November 1395 to 1786 they have been preserved intact, and form twenty-four folio parchment volumes written by hand in Latin These Wickersheimer has edited and published, down to 1516 in a quarto volume of 561 pages——Another prize went to Maillard for his synthetic production of polypeptids by submitting amino acids to the action of glycerin The *Bulletin* of the Academie, No 49, gives the list and conditions for the numerous prizes open to competition in 1917, 1918 and 1919

PARIS LETTER

Paris, Dec 21, 1916

The War

TRENCH FOOT

The directors of the health service at the main army headquarters have sent to the hospitals a paper by Drs Raymond and Parisot on freezing of the feet, commonly called trench foot It states that this affection is particularly grave among the Indian troops, a number of whom are afflicted not only with serious and extensive local lesions, but also with symptoms of a general septicemia, accompanied by thermal blisters, adynamia, frequent epistaxis, and sometimes by collapse At the outset, this condition may resemble typhoid, subsequently developing into a serious icteric state, pulmonary congestion or nephritis These complications may result fatally, the necropsy in such cases revealing impairment of the liver, spleen, lungs and kidneys, and organic mycosis Inoculation of animals with the bile taken from these patients under aseptic conditions produces the blister and eschar characteristic of trench foot This septicemic condition, as observed in the Indian troops, is also found in Europeans in serious cases Raymond and Parisot have succeeded in overcoming the disease among French soldiers without loss of toes by employing the following treatment

1 The feet are bathed in lukewarm water with ordinary and borated camphor soap, the suds must be mild so as not to irritate the foot The nails should also be manicured, care being taken not to injure the toes

2 A dressing well moistened with borated camphor solution is applied This dressing is made by applying loosely to the foot, taking care to include the nails a layer of absorbent cotton about an inch thick, wrapped in gauze and soaked in a solution of borated camphor Over this is placed an ample covering of adhesive tape, and the entire dressing is stabilized with a band Caution must be used not to bind the foot in any way This dressing should remain moist until the next day, when it is removed It is necessary to renew the dressing daily until the edema has totally disappeared, which usually occurs between the second and fourth day, when the impermeable dressing is discontinued for a day or two Treatment is then limited to daily unctions of camphorated oil until a cure is effected Camphorated alcohol, which is undesirable in such cases, should be avoided

3 If the blisters are no larger than 2 centimeters, they can be left unopened as they heal with the treatment of the edema Larger, or hemorrhagic, blisters should be aseptically excised, the underlying skin removed and the blisters then dressed with compresses saturated with a solution of 30 gm of camphor in 1 000 gm of ether The usual dressing is employed until all traces of edema have disappeared, it is then followed by a camphorated ether dressing

4 In serious cases accompanied by fever, it is advisable to inject camphorated oil hypodermically in doses of from 5 to 10 c c daily

5 As tetanus is to be particularly guarded against, it is well always to give a prophylactic injection to each patient This injection should be repeated every eight days when ulceration develops, the dose being doubled in serious cases (Pasteur serum 20 c c, or American serum, 3,000 units)

6 Finally, it is important to apply the treatment early transporting the patients to the nearest field hospitals where they may receive immediate care Under these conditions the average period of treatment is from twelve to fifteen days

Transportation facilities have just been perfected whereby soldiers suffering with frozen feet may be brought from the front for prompt attention Dr Chavasse general director of the health service of the army in the field in transmitting the paper by Drs Raymond and Parisot emphasizes the great advantage in using the treatment described the splendid results of which as compared with those of other known methods he has been able to appreciate

EFFECT OF CRANIAL WOUNDS ON FITNESS FOR ARMY SERVICE

The fitness for army service of those who have received cranial wounds has been the subject of much discussion At a meeting of the members of the neurologic society of Paris and the representatives of the military neurologic centers (The Journal, July 1 1916 p 47 and July 22 1916 p 297) the problem was discussed and the decisions then made have just been adopted by the undersecretary of state of the military health service It has been decided to exclude from the service those with cranial wounds who are affected with serious organic disorders of the nervous system manifestly incompatible with any kind of military service (such as hemiplegia, monoplegia, difficulty of speech, loss of a large part of the skull, etc) It is also necessary in each case to search carefully for a certain number of other disorders which are of considerable importance from a prognostic point of view, such as chronic cephalalgia, dizziness, vertigo, aural and visual trouble, mental derangements, emotional, sympathetic, circulatory, secretory reactions and finally hyperalbuminosis of the cerebrospinal fluid, etc As to the manner of dealing with those afflicted with any of these disorders, it is difficult and undesirable to establish any arbitrary rule In fact, the peculiarities of each case should be considered separately In general however, no soldier who has received a cranial wound should return to the front except in markedly exceptional cases and after prolonged observation

LONDON LETTER

London, Dec 23, 1916

The War

DISABLED SOLDIERS

The report of a committee of the Royal Colleges of Physicians and Surgeons on the medical treatment of dischargeable disabled soldiers has just been issued It deals only with soldiers not yet discharged from the army The case of soldiers already discharged is now under consideration and will form the subject of a further report The committee has agreed to the following conclusions 1 A considerable proportion of disabled soldiers require continued institutional treatment 2 An essential condition of success is that the patient be throughout under discipline and that no form of discipline can adequately replace military discipline 3 Consequently a disabled soldier should not be discharged from the army until a specially constituted board of medical experts has decided that no further institutional treatment will improve his condition provided such treatment does not extend beyond some general maximum limit to be determined by the military authorities 4 They should be retained in military hospitals until they are fit to be discharged to convalescent camps or other suitable institutions or to return to their own homes 5 On their discharge from military hospitals, such of them as are likely to benefit by institutional treatment should be transferred to annexes to the existing convalescent camps, or to such other camps as may be set up officered by members of the army medical corps to whom civilian help should be supplied 6 In the camps their treatment should be as far as possible, the same as that of soldiers who are expected to return to active duty, except that curative manual treatment including technical and mechanical training should in many cases, take the place of military exercises 7 Several kinds of special boards will be necessary (*a*) For general cases, the board should consist of one physician, one surgeon and a third officer (*b*) for ophthalmic cases, one physician, one ophthalmic surgeon and a third officer, (*c*) for neurasthenic cases and epileptic cases one physician, one neurologist and a third officer, and (*d*) for mental cases, one physician, one alienist and a third officer

A STATE MEDICAL SERVICE

I have stated before that from the insurance act a state medical service in which the physicians would be whole time state officials would probably develop For some time a controversy has been going on in the *Times* and in medical journals on the subject and the war has provided the advocates of a state service with a new argument The attempts to conserve the practices of the large number of physicians (practically every one up to the age of 41) who have joined the army have not been very successful It was arranged that their neighbors would attend their patients for them and retain only a proportion of the fees, but the practices have shown a constant dwindling with the protraction of the war Consequently a fund has been opened to which the profession is invited to subscribe for the purpose of lending money to physicians on their return from the war to buy practices Then in the lay press attention was called to the exceedingly efficient army medical organization for the treatment of all the diseases and injuries of the soldiers, and the question was raised why the state should not organize in civil life an equally efficient system for the civilian population It was pointed out that the physicians who had joined the army were thoroughly trained in this system and would be able to place their experience at the services of the public Moreover, the giving of state appointments would be a far better way of recognizing their patriotism than the suggested loan fund Curiously this further development of socialism has been strongly advocated in the *Times* which, like the rest of the conservative press, at the time of its passage offered the most virulent opposition to the insurance act In these days when the necessity for the state controlling almost all the activities of life is undisputed, the cry of socialism which confronted all social reforms, good or bad, has been silenced On the other hand, what remains of the civilian medical profession is strongly opposed to the proposal, and the British Medical Association has condemned it The association has exposed itself to the taunt of having done so before any details were brought forward The panel physicians are also opposed to the proposal, and their organization is again considering the advisability of forming a trade union so as more effectively to protect their interests in this as well as in other respects

Epidemic of Influenza in London

A widespread epidemic of influenza is prevailing in London It is of a mild type, however, and manifests itself only by slight fever and general aching lasting only a few days and attended by very little or no catarrh of the respiratory mucous membrane In the last four weeks the deaths from the disease have numbered only 17, 41, 55, and 81, respectively

The Fallibility of Dying Declarations

According to the law of this country, the declaration of a person who is dying, and knows the fact, is admitted in the courts as evidence of equal value to that given on oath, and such evidence has often been the means of convicting criminals That it is not always reliable is shown by the following case A woman was dying as the result of an illegal operation for abortion She made three separate 'dying declarations" which were admissible, therefore as evidence They showed minor variations, but substantially agreed in attributing to a physician two unsuccessful attempts to induce abortion followed by a successful and fatal attempt by a woman Fortunately the physician kept his books in good order, and by means of them was able to show that the woman had seen him only once when she gave a false name paid him 4 shillings and received from him a prescription for a tonic According to his evidence she requested him to undertake an illegal operation which he refused He was therefore vindicated Presumably the fear of death was not sufficient to deter the woman from making a false accusation A motive which has been suggested was the desire for revenge because the physician refused her request Another possibility is that she was under some delusion in the matter

---

Marriages

John Marshall Page M D, Littleton N H, to Miss Agnes L Greene of Cambridge, Mass, at Alston, Mass, December 24

Robert Garfield Pearson, M D, Sacramento Calif, to Miss Margaret E Crawford of Philadelphia, at Sacramento November 9

Stephen Decatur Harrison, M D, Brooklyn, to Miss Louise Hunter of Cornwall-on-Hudson, N Y, at Brooklyn, December 28

William Barnard Sharp M D, Shanghai China, to Miss Alice Percy of Anaconda, Mont, at Helena, December 22

Charles Chapin Childs M D, Niagara Falls, N Y, to Miss Eva Saunders of Baltimore, December 20

Arnold Noble Allen M D Boston, to Miss Blanche A Greenaway of Roslindale, Mass, December 23

Edward Giles McConnell, M D to Miss Elizabeth M Scott, both of San Francisco, December 26

Orville Jackson Walker M D, Oklahoma City, to Miss Mary Getty of Wilmington, Pa, recently

Thomas Abram Boger, M D, Milwaukee, to Miss Camille Collins of Waukesha, Wis, December 20

W Harman Evans M D, to Miss Agnes Irene McGregor both of Lynchburg, Va, December 24

Elmer Walker Barron, M D, Boston, to Miss Ruth Stanwood Patch of Malden, December 25

Benjamin F Sturgis Jr, M D to Mrs E Janet Sherry both of Salem, Mass, December 25

Lucky Fred Lundy, M D, Seattle, Wash, to Miss Ruby Leedom of Omaha, December 23

Deaths

Hamilton Wright, M D, Washington, D C, McGill University, Montreal 1895, aged 49, died at his home in Washington, D C, January 9 Dr Wright is probably best known as one under whose guiding hand the Harrison Narcotic Law and other federal legislation for the regulation of the sale of habit-forming drugs developed and became laws He had, however, an international reputation even before he entered on that work, having served from 1899 to 1903 as assistant director of the London County (England) laboratories, during which time he was sent by the British government to the Malay states to study beriberi and other tropical diseases While engaged on this mission he founded the Institute for Medical Research in the Federated Malay States and Straits Settlements In 1909 he was appointed by President Roosevelt as one of the United States Commissioners to attend the International Opium Convention in Shanghai Later he was retained by the Department of State to take charge of affairs growing out of that convention, and served as one of the United States delegates to the international opium conferences, held at the Hague in 1911 and 1913 In 1915, Dr Wright went to France to assist in relief work, and while there was seriously injured in a motor accident, from which he never fully recovered His death however, was the result of pneumonia

Tarleton Hoffman Bean, M D, Smithtown Branch N Y George Washington University, Washington, D C, 1876, aged 70, a veteran of the Civil War assistant in charge of the Division of Fish Culture and Curator of the Department of Fishes in the United States National Museum from 1880 to 1895, director of the New York Aquarium from 1895 to 1898 and since 1906 state fish culturist, an honorary member of the Danish Fishery Society, editor of the *Proceedings and Bulletin of the United States National Museum* from 1878 to 1886, president of the American Fisheries Society in 1908 and 1909 a scientist of great renown in his specialty, who had received decorations from France, Germany and Japan, died in Albany, December 28, as the result of injuries sustained in an automobile accident two months before

Samuel Anderson McWilliams, M D, Chicago, Northwestern University Medical School 1866 aged 81, a Fellow of the American Medical Associatioon, formerly lecturer on urinary and renal disorders in his alma mater and later professor of anatomy in the Northwestern University Woman's Medical School, one of the organizers of the College of Physicians and Surgeons Chicago and later one of the founders of the Chicago Hospital College of Medicine, professor of diseases of the chest clinical medicine and physiology in Reliance Medical College, Chicago, a specialist in physical diagnosis, died at his home, January 4, from arteriosclerosis

Charles Henry Rice, M D, Fitchburg Mass, Harvard Medical School 1866, aged 73, formerly a Fellow of the American Medical Association, a member and once vice president of the Massachusetts Medical Society, consulting surgeon to the Burbank Hospital, Fitchburg, formerly major surgeon of the Sixth Infantry, Massachusetts Volunteer Militia and retired in 1897 as lieutenant colonel, first city physician of Fitchburg and first chairman of the board of health, for twenty-five years a member of the board of trustees of the public library and for sixteen years a member of the school board, died at his home, January 5

DeWitt A Paine, M D, Eugene Ore Hospital College of Medicine Louisville Ky, 1887, aged 63, formerly a Fellow of the American Medical Association and president of the Lane County Medical Society, president of the Eugene Loan and Savings Bank and of the United States National Bank, Eugene, consulting surgeon for the Southern Pacific Railroad superintendent of the Oregon Insane Asylum from 1895 to 1901, died suddenly at his home from cerebral hemorrhage December 27

William Wallace Rodman, M D, Pierce City, Mo, College of Physicians and Surgeons, Keokuk Iowa 1875 aged 62, formerly a Fellow of the American Medical Association a member of the Missouri State Medical Association, and Association of Military Surgeons of the United States formerly major surgeon of the Second Infantry, Missouri National Guard died in Kansas City Kan, December 19, from cerebral hemorrhage

Jesse Houck Ramsburgh, M D, Washington D C University of Virginia, Charlottesville, 1895, aged 47, a Fellow of the American Medical Association, a member of the faculty of Georgetown University Medical College, a member of the staff of Georgetown University Hospital, chief of clinic of the Free Dispensary for Consumptives, prominently identified with the tuberculosis movement in the district, died in the Emergency Hospital, Washington, January 2, from cerebral hemorrhage

Edward Boicourt Trovillion, M D, Boulder, Colo, Rush Medical College, 1885, aged 55 a Fellow of the American Medical Association and president of the Boulder County Medical Society in 1912, for several years professor of anatomy in the University of Colorado, health officer of Boulder County for five years, died in the University Hospital, Boulder December 23 from tumor in the head of the pancreas and cirrhosis of the liver

Hulbert H Clark, M D, Santa Cruz, Calif, Medical College of Ohio, Cincinnati 1871 aged 81, formerly a Fellow of the American Medical Association acting assistant surgeon U S Army during the Civil War, formerly local surgeon of the Chicago and Eastern Illinois Railroad, coroner and public administrator of Santa Cruz County from 1894 to 1898 and in 1896 mayor of Santa Cruz, died at his home December 26

Henry H Amos, M D, Charles City Iowa, King Eclectic Medical College, Des Moines, Iowa 1888 aged 58, formerly a Fellow of the American Medical Association and president of the Floyd County Medical Society a specialist on diseases of the eye, ear, nose and throat, local surgeon to the Chicago, Milwaukee and St Paul Railroad died suddenly in a drug store in Charles City, December 19 from heart disease

William E Whitney, M D, Eldora, Iowa, Rush Medical College 1891, aged 61, a Fellow of the American Medical Association surgeon to the Iowa State Industrial School, boys' department, and assistant superintendent of the institution at one time superintendent of the Orphan's Home Davenport and also deputy sheriff of Hardin County died at his home, January 3, from cerebral hemorrhage

Joseph Weatherhead Warren, M D, Harrisburg Pa University of Bonn Germany, 1880, aged 67, assistant to the state commissioner of health demonstrator of anatomy and instructor in Harvard Medical School from 1881 to 1891, and from 1891 to 1913 professor of physiology in Bryn Mawr College, died in Keystone Hospital Harrisburg, December 20 from disease of the kidney

Jean J Dumortier, M D, South Norwalk Conn University of Ghent Belgium 1890, aged 51 a Fellow of the American Medical Association, a member of the staff and president of the Norwalk Hospital once health officer of South Norwalk was found dead at his home December 13 having taken his life by strangulation while of unsound mind on account of ill health

Frank M Galer, M D, Degraff, Ohio, Starling Medical College Columbus, Ohio 1867, aged 73, a member of the Ohio State Medical Association, president of the Citizens Bank Degraff and vice president of the United Telephone Company, a member of the city council and board of education of Degraff died at his home January 1, from kidney disease

Paul Monroe Pilcher, M D, Brooklyn College of Physicians and Surgeons in the City of New York 1900, aged 40 a Fellow of the American Medical Association and a specialist in abdominal surgery, consulting surgeon to the East Long Island Hospital, first editor of the *Long Island Medical Journal* died at his home, January 4 from pneumonia

Peter John Livingstone, M D, Detroit, University of Michigan, 1892, aged 51, a Fellow of the American Medical Association, a member of the American Academy of Ophthalmology and Oto-Laryngology a specialist on diseases of the eye ear nose and throat, died at his home December 28, from cerebral hemorrhage

George W Grabenstatter, M D, Buffalo, University of Buffalo 1900, aged 42, a Fellow of the American Medical Association, for two years acting assistant surgeon, U S Army with service in the Philippine Islands died at the Buffalo General Hospital, January 3, nine days after an operation for appendicitis

Charles Michael McLaughlin, M D, Greencastle Pa Jefferson Medical College 1889, aged 55, a Fellow of the American Medical Association, and once president of the Cumberland Valley Medical Association, a member of the board of health of Greencastle, died at his home, January 6 from chronic endocarditis

Joseph A E Reed, M D, Lancaster, Pa , Pennsylvania Medical College, Gettysburg, Pa , 1854, aged 84, formerly a Fellow of the American Medical Association, a member of the Medical Society of the State of Pennsylvania, a surgeon of volunteers throughout the Civil War, died at his home, January 3

Frederick W Fochtman, M D, Cumberland, Md , College of Physicians and Surgeons, Baltimore, 1889, aged 49, a Fellow of the American Medical Association, a pioneer Roentgen-ray operator of western Maryland, was found dead in his automobile at Ellerslie, January 5, from cerebral hemorrhage

William F Ingram, Kaysville, Utah (license, five years' practice, Utah, 1894), aged 76, formerly a member of the Utah State Medical Association, for more than forty years a practitioner of Davis County, a veteran of the Civil War, died at the home of his son in Bristol, R I, December 7

John Willard Meeker, M D, Brooklyn, New York University New York 1863, aged 82, for forty years a druggist of Williamsburg, and for a time a surgeon in the army, a charter member of the New Jersey Microscopical Society, died at his home, January 1, from pneumonia

John L Hoshall, M D, Oklahoma City, College of Physicians and Surgeons, Baltimore, 1899, aged 43, a member of the Oklahoma State Medical Association, was accidentally killed, January 4, by a collision between the automobile in which he was riding and another car

Roy Gavin Fisher, M D, Tucson, Ariz , Dearborn Medical College, Chicago, 1907, College of Physicians and Surgeons, Chicago, 1909, aged 33, formerly professor of ophthalmology in the Chicago Eye, Ear, Nose and Throat College, died at a hospital in Tucson, December 26

Harry Blair Warriner, M D, Philadelphia, Maryland Medical College, Baltimore, 1912, Hahnemann Medical College, Philadelphia, 1914, aged 28, chief resident physician at the Children's Homeopathic Hospital, died in that institution, January 4, from pneumonia

George Everett Titus, M D, Hightstown, N J , Bellevue Hospital Medical College, 1877, aged 61, a Fellow of the American Medical Association, at one time a member of the common council of Hightstown, died at his home, January 4, from cerebral hemorrhage

George Clary, M D, New Britain, Conn , Yale University New Haven, Conn , 1857, aged 87, a member of the Connecticut State Medical Society, surgeon of the Thirteenth Connecticut Volunteer Infantry during the Civil War, died at his home, December 30

Elias L Kinyon, M D, Brighton, Colo , Eclectic Medical Institute, Cincinnati, 1899, aged 52, died at his home, January 4, from the effects of a gunshot wound of the head, self-inflicted, it is believed with suicidal intent, while despondent on account of ill health

Ernest Samuel Feagin, M D, Mobile, Ala , University of Alabama Mobile, 1905 aged 35, a member of the Medical Association of the State of Alabama, for five years house physician of the City Hospital, Mobile, died suddenly at his home, December 30

Albert Weeks, M D, Phoenixville, Pa , Jefferson Medical College, 1880, aged 58, formerly a Fellow of the American Medical Association, one of the organizers of the Stratford Castle Hospital Phoenixville, died at his home, December 27, from erysipelas

Edmund T Spotswood, M D, Terre Haute, Ind , Rush Medical College 1851, aged 90, surgeon of the Seventy-First Indiana Volunteer Infantry during the Civil War, a member of the legislature in 1858, died at his home, January 5, from senile debility

Alphonse Louis Eakin, M D, Philadelphia, University of Pennsylvania, Philadelphia, 1863, aged 77, died at his home, January 2, after an invalidism of several years, due to a wound received while serving as a medical officer in the Civil War

John S Sellers, M D, Hartford City, Ind , Medical College of Indiana, Indianapolis, 1888, aged 72, formerly a Fellow of the American Medical Association and a member of the Indiana State Medical Association, died at his home, January 3

Carl Shadiker Adams, M D, Colorado Springs, Colo , Harvard Medical School, Boston, 1902, aged 42, a specialist on dermatology, a member of the Colorado State Medical Society, died at his home, about January 1, from tuberculosis

William Clarence Kluttz, M D, El Paso, Texas, University of Pennsylvania, Philadelphia, 1899, aged 40, a Fellow of the American Medical Association, and a member of the American Association of Railway Surgeons, died, January 4

Erich A Hermsmeier, M D, Milwaukee, College of Physicians and Surgeons, Memphis, Tenn , 1911, aged 28, a Fellow of the American Medical Association, died at his home, December 28, from pneumonia complicating influenza

Kenton Harper Trimble, M D, Monterey, Va , University of Virginia, Charlottesville, 1884, Bellevue Hospital Medical College, 1885, aged 57, a member of the Medical Society of Virginia, died at his home, December 22

John T Fugate, M D, Urbana, Ill , Missouri Medical College, St Louis, 1859, aged 86, one of the oldest practitioners of central Illinois, died at the home of his daughter in Urbana, December 25, from senile debility

Richard Edward Sweeney, M D, New York, Niagara University, Buffalo, 1898, aged 39, died in the Gouverneur Hospital, New York, December 25, from burns sustained by the accidental upsetting of an oil stove

Charles Cleveland Frederick, M D, Lizella, Ga , Medical College of Georgia, Augusta 1912, aged 29, a member of the Medical Association of Georgia, died at the home of his sister in Macon, about December 21

James Bingham, M D, Washington, Pa , Western Reserve University, Cleveland, 1868, aged 84, for forty-two years a practitioner of Clinton, Pa , died at the home of his daughter in Washington, Pa , December 25

Benjamin Franklin Hopkins, M D, Hot Springs, Va , Jefferson Medical College, 1855, aged 88, a member of the Medical Society of Virginia, died at the home of his daughter in Staunton, Va , December 26

Erastus H Cummings, M D, Grand Rapids, Mich , Hahnemann Medical College, Chicago, 1877, aged 81, a veteran of the Civil War, in which he served as a hospital steward, died at his home, December 20

Charles Edwin Stone, M D, Lynn, Mass , University of Vermont, Burlington 1906, aged 48, a member of the Massachusetts Medical Society, died in the Lynn Hospital, November 5, from chronic nephritis

Sarah Abbie Jenness, M D, Wolfeboro, N H , Boston University, 1889, aged 70, for many years a practitioner of Boston, was burned to death in a fire which destroyed her home December 26

Wilson L Kutz, M D, Weissport Pa , Jefferson Medical College, 1878, aged 62, a Fellow of the American Medical Association, died at his home, December 23, from malignant disease

Ellera J Whittleton, M D, Webster N Y , Homeopathic Hospital College, Cleveland 1884, aged 57, died at his home, November 20 from cerebral hemorrhage

Francis Lamb Howland, M D, Huntsville, Ont , McGill University, Montreal, 1867, aged 74, died at his home, November 8 from chronic nephritis

Russell Henry Nevins, M D, Waterford, Conn , College of Physicians and Surgeons in the City of New York, 1876, died in New York, December 21

James Kiron Dorsey, M D, Wichita, Kan , New York University, New York, 1892, aged 46, died at his home, December 24, from pneumonia

James Harry Ralston, M D, Kansas City, Mo , Medico-Chirurgical College of Kansas City, 1904, aged 45, died at his home, about December 29

Richard Edward Cavanaugh, M D, Duluth, Minn , Rush Medical College, 1894, aged 48, died at his home, December 24, from heart disease

William Ferdinand Radue, M D, Union Hill, N J , New York University, New York, 1888, aged 55, died at his home, December 26

Charles E Caldwell, M D, Chicago, Rush Medical College, 1877, aged 65, died at his home, January 5, from pneumonia

Sarah J Millsop, M D, San Diego, Calif , Hahnemann Medical College, Chicago, 1886, died at her home November 2

John Becker, M D, Chicago, Rush Medical College, 1865, aged 87, died at his home, December 29, from tuberculosis

Edwin Mayo Bangs, M D, Ithaca, N Y , Boston University School of Medicine, 1878, died at his home, December 24

Alexander Gaertner, M D, Boston, University of Jurjev, Russia, 1889, aged 56, died at his home, December 30

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

ASPIRIN

Report of the Council on Pharmacy and Chemistry

The referee's report on Aspirin-Bayer which follows was submitted to the Council and adopted by it and, in accordance with the referee's recommendation, was sent to the Bayer Company Inc The company's reply contained nothing to warrant the continued recognition of this product by the Council It was accordingly directed that Aspirin-Bayer be omitted from New and Nonofficial Remedies

W A Puckner, Secretary

REFEREE'S REPORT

The referee's attention has been called to the systematic campaign of advertising aspirin to the public He is informed that tablets have been marketed for some time in 'vest-pocket' boxes bearing the name 'Aspirin' permanently affixed, which is in technical conflict with the Council's rule against indirect advertising to the public More recently conspicuous advertisements have appeared in daily papers These are technically in conflict with the rule against direct advertising to the public

In addition to the plain technical conflicts with the Council's rules there is a feature of the case which has not hitherto been raised and which should be fully considered It may be remarked that the advertisements contain no therapeutic recommendation, and do not, on their face urge the public to employ aspirin but apparently merely tell the public how it may protect itself against sophistication In substance, they say If you are a user of aspirin, this is how you may obtain the genuine" It might be said that this is not an attempt to increase the use or sale of aspirin—the ordinary object of advertising—but that the means of protection against adulteration is a 'subject on which the public should be instructed' The principle of such exceptions is stated in the comments to Rule 3 (New and Nonofficial Remedies, 1916 p 15), and although the present case does not come under the exceptions specified under these comments it may be urged that the exceptions need to be increased as occasion arises The notorious adulteration of aspirin may well be urged as establishing a need for a similar exception in its use

The general principle of protecting the public against fraud, adulteration and substitution is directly in line with the objects of the Council, and deserves commendation and support It is obvious however, that the means adopted for this end must be efficient, that they must not open the door to other, perhaps greater evils and that they must be used in good faith The policy of advertising Aspirin-Bayer must be examined in these respects

In the first place the acceptance of a product by the Council implies an agreement by the manufacturers or agents that they will adhere strictly to the Council's rules and will not depart from the letter or spirit of these rules without notice to the Council This principle has been grossly infringed in the present case There can be no doubt that the agents were aware that their advertisements conflicted at least with the letter of Rule 3 Nevertheless, they did not, in any way, inform the Council of the change in policy In this respect, at least, they have not acted in good faith

Secondly, the wording of the advertisement implies that only the tablets stamped with The Bayer Cross" are genuine. This is misleading since every druggist has the right to make unstamped tablets of aspirin, fully as genuine as those stamped with the cross

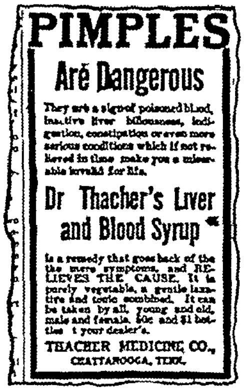
Thirdly, the cross itself cannot be considered an efficient protection, for people who imitate aspirin will not hesitate to imitate the stamp The remedy, in either case, and as with any other drug, is the examination of trade samples and the vigorous prosecution of those guilty of violating the law

Fourthly, the permanent affixing of the name "Aspirin' to the vest-pocket boxes is also inefficient as a protection, and serves mainly as an advertisement

Fifthly, whatever may have been the motives of the advertisers and however carefully the advertisements are worded they will inevitably tend to increase the use of aspirin by the public, and this is directly against the interests of public health The public does not know as physicians do, that headaches are merely symptoms of other, sometimes very serious conditions, and that they are often the signal for the need of a thorough physical examination and diagnosis It is true that they are often also the symptoms of very minor derangements, which will right themselves spontaneously and that, in such cases drugs like aspirin may give relief and may do no harm The patient however, is not educated to distinguish one class from the other and therefore anything that tends to promote the indiscriminate use of such remedies as aspirin is detrimental to the public health Furthermore, aspirin itself is not always harmless Alarming idiosyncrasies are sufficiently common that the use of the first doses at least, should require medical supervision With these considerations in mind, the referee is of the opinion that the direct and indirect advertising of aspirin is to be condemned

MORE MISBRANDED NOSTRUMS

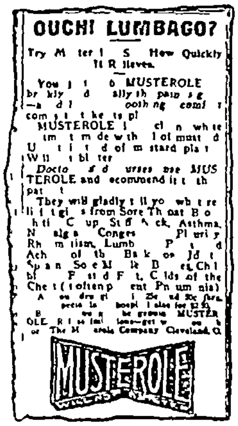
Dr Thacher's Liver and Blood Syrup—This preparation, which admittedly contained 12½ per cent alcohol was sold by the Thacher Medicine Company Chattanooga, Tenn The claims made by the company that the stuff contained no aloes but contained potassium iodid and sarsaparilla combined with May apple, gentian juniper berries buchu leaves dandelion root and yellow dock root were declared by the government to be false and misleading It was further claimed by the company that Thacher's Liver and Blood Syrup would cure All Liver Complaints Biliousness Costiveness Drowsiness Yellow Jaundice And All Liver Complaints Impure or Bad Blood including Scrofula, Salt Rheum Erysipelas, Pimples and all Diseases of A Syphilitic Character, Also Loss of Appetite Dyspepsia Sour Stomach Sleeplessness Pains in Back and Sides Sick Headache " Naturally the government declared these claims misleading false and fraudulent As no claimant appeared for the property the court ordered that it should be destroyed by the United States marshal—[*Notice of Judgment No 4351*]



PIMPLES
Are Dangerous
They are a sign of poisoned blood, inactive liver biliousness, indigestion, constipation or even more serious conditions which if not relieved in time make you a miserable invalid for life.
Dr Thacher's Liver and Blood Syrup
Is a remedy that goes back of the the mere symptoms, and RELIEVES THE CAUSE. It is purely vegetable, a gentle laxative and tonic combined. It can be taken by all, young and old, male and female. 50c and $1 bottles at your dealer's.
THACHER MEDICINE CO.,
CHATTANOOGA, TENN.

Black's Pulmonic Syrup—W F Black and W H Martin who did business under the name Black Distributing Agency, Nashville Tenn put on the market Black's Pulmonic Syrup" which was alleged to contain 20 per cent alcohol and to be Compounded by W F Black M D Birmingham Alabama It was sold as The New Remedy for Tuberculosis and Bronchitis Government chemists reported that it was a water-alcohol solution of ichthyol glycerin and sugar Government officials declared naturally, that the claim that this stuff was an effective remedy for tuberculosis was false and fraudulent and applied knowingly recklessly and wantonly Both defendants pleaded guilty and Black was fined $200, Martin $100 and the costs assessed on both—[*Notice of Judgment No 4357*]

Walker's Pain Destroyer—This stuff was made and sold by Sarah Ann McDonald who conducted her nostrum business under the name of Walker Medicine Co, St Paul Minn It was sold as a sure cure for Diphtheria and all Throat Diseases Summer Complaint, Felons, Chilblains Frost Bites Neuralgia and is remarkable in Rheumatism The government chemists reported that analysis "showed that the product was an alcoholic solution of oil of mustard, chloroform, opium and collodion" The therapeutic claims were declared by the government to be false and fraudulent and made knowingly and in reckless and wanton disregard of their truth or falsity The further claim made for the stuff that it was "invaluable in the household and nursery and no danger whatever can ensue from an overdose, as there are no poisonous ingredients in the compound" was declared false and misleading in view of the fact that the stuff contained chloroform and opium The defendant pleaded guilty and was fined $5—[*Notice of Judgment No 4353*]



OUCH! LUMBAGO?
MUSTEROLE
MUSTEROLE
MUSTEROLE

Musterole—This product, marketed by the Musterole Co, Cleveland, Ohio, was analyzed by the government chemists who reported that it was essentially a mixture of lard or some similar material with oil of mustard, menthol and camphor Claims made for the preparation were to the effect that it would cure pneumonia, asthma, bronchitis, croup, rheumatism and pleurisy and would prevent pneumonia These claims were declared false and fraudulent and applied knowingly, recklessly and wantonly The company would neither affirm nor deny the charge but was found guilty and fined $25 and costs—[*Notice of Judgment No 4358*]

Snyder's Bitters—The J H Snyder Medicine Co, Jonesboro, Ark, sold Snyder's Bitters under the claims that it contained 20 per cent alcohol, and would eradicate "Scrofula, Scrofulous Humors, Syphilitic Affections, Cancerous Humors, Ringworms, Salt Rheum Catarrh and all diseases arising from an impure state or low condition of the blood" It was also said to be an "Unfailing Relief for Indigestion and all Diseases of the Liver and Kidneys" as well as a cure for malaria, to say nothing of being "an absolute panacea for all diseases and disorders of the female genital organs" These claims were declared false and fraudulent and applied knowingly, recklessly and wantonly The company pleaded guilty and was fined $10 and costs—[*Notice of Judgment No 4359*]

5 Drops—"5 Drops" was put on the market by the Swanson Rheumatic Cure Co, Chicago, Ill It was sold as a remedy for rheumatism, sciatica, asthma, hay fever, croup, la grippe, catarrh and malaria, as a preventive of germ diseases and as a cure for blood diseases, eczema scrofula and gastric ulcer as well as a preventive of gallstones The government chemists reported that analysis showed the stuff to consist of "a mixture of eucalyptol (or a eucalyptol-containing oil), camphor, safrol, terpineol and eugenol (or an oil containing those ingredients, such as camphor oil)" The government declared the curative claims to be false and fraudulent and applied knowingly, recklessly and wantonly The company pleaded guilty and was fined $200 and costs—[*Notice of Judgment No 4372*]

Dr Stuart's Specific Drops—Joseph W and Anna B House sold "Dr Stuart's Specific Drops" under the name Stuart Remedy Co, Detroit, Mich Claims made for the nostrum were that it was a cure for rheumatism and a positive specific for eczema and salt rheum and would drive all impurities out of the blood The government chemists reported that the preparation was essentially a mixture of camphor, alcohol, mercuric iodid and turpentine The curative claims were declared false and fraudulent and applied knowingly, recklessly and wantonly The defendants pleaded guilty and were fined $50—[*Notice of Judgment No 4368*]

Correspondence

Secret Remedies and Professional Responsibility

To the Editor—A man of great wealth and of social and business prominence in this community recently returned from an eastern visit during which he had occasion to consult a physician The physician, be it remarked, is a prominent educator, being dean of one of the most important medical schools of the country, a man of nation wide reputation, and of undoubted skill and ability as a practitioner of medicine He is also well known in the American Medical Association, of which he has long been a prominent and important Fellow, and is a vigorous enemy of secret remedies and a strong supporter of the Council on Pharmacy and Chemistry The above mentioned gentleman brought home with him a new and marvelous remedy which his physician had prescribed for him and which in an incredibly short time had cured his influenza and which, as grip was quite epidemic at home among his friends, he immediately recommended to several of them There is no greater joy to the average nonmedical person than to be able to advise a new remedy for one's friends' ailments, especially one so highly recommended, and as a result there was an immediate and large demand for this preparation, greatly to the profit of the local drug stores as well as of the manufacturer The remedy, a secret proprietary which has not been accepted by the Council and cannot be advertised in The Journal, is a preparation which has long been on the market, is freely sampled to physicians in an attractive container and accompanied by the usual extravagant claims to cure many of the common diseases, and is recommended both for internal and external use This incident is related to show how sometimes our most ethical brethren help to boost the secret remedy

Burnside Foster, M D, St Paul

HEMATOXYLIN STAIN—DIAGNOSTIC VALUE OF VON PIRQUET REACTION

To the Editor—In the April, 1916 issue of the *Comptes rendus des séances et mémoires de la Société de biologie*, Paris Triboneau Fichet and Dubriel describe a new hematoxylin stain—silver hematemate The abstract I have gives no details as to its preparation

1 Please publish the detailed method of preparing this stain

2 Please give briefly the exact diagnostic value of the von Pirquet test

Robert Kilduffe M D Chester, Pa

Answer—1 (*a*) Preparation of Silver Oxid In a carefully cleaned stoppered bottle dissolve 1 gm of silver nitrate in 100 c c cold distilled water Add to this quickly 50 c c of a 10 per cent aqueous solution of pure potassium hydroxid Shake well Let stand for one minute, decant from the heavy precipitate of silver oxid Wash this by decantation with four lots of 150 c c of distilled water, each (*b*) Preparation of Silver Hematemate Dissolve 2 5 gm of French hematoxylin in 50 c c of absolute alcohol Pour this on the silver oxid Place the mixture in a long-necked flask, and heat on the water bath with occasional shaking until the alcohol boils The liquid should be of a deep orange color Filter (*c*) Preparation of Silver Hemalum Staining Solution To one part of the silver hematemate solution add twenty parts of a 5 per cent solution of potassium alum

2 It is not possible within the limits of a short answer to discuss satisfactorily the diagnostic value of von Pirquet's reaction The following is a partial list of the literature on the subject published within the last two years

REMOVAL OF BURNT POWDER FROM THE SKIN

To the Editor—Please give me the best treatment for removing burnt powder from the skin, the result of a pistol shot

W H Smith M D Goldsboro, N C

Answer—A reply to this question appeared in Queries and Minor Notes, The Journal, Nov 14 1908, p 1716 In brief, it was stated that if the patient is seen shortly after the accident, the gunpowder grains can be picked out readily Much of the powder can be removed by the same process later on, although this is tedious and difficult Watson and Keyes advocated the use of a cutaneous punch or trephine similar to that used for removing comedones The punch is placed over the powder mark and pressed down firmly Care should be taken not to enter the skin too deeply The small portion of skin which projects from the trephine can be snipped off and a soothing ointment applied Hydrogen peroxid is sometimes used, either full strength or three parts to one of glycerin Crile applies hydrogen peroxid until it has penetrated under the powder grains, the effervescence forcing them out of their bed

In case the powder marks are old, they may be removed in the same manner as tattoo marks Methods of doing this are described by W A Pusey, "Principles and Practice of Dermatology," in the chapter on 'Tattoo Marks and Powder Stains," p 814 and also in Queries and Minor Notes, The Journal, July 22 1911, p 310, Sept. 12, 1912, p 895, and Jan 24, 1914, p 315

TREATMENT OF SEBORRHEA OF SCALP

To the Editor—In my books on skin diseases I find no lotions for seborrhea of the scalp except those containing resorcin This is so scarce and high priced that I cannot use it Could you give one or more formulas containing drugs that may be substituted for resorcin?

George G Smith M D Chagrin Falls Ohio

Answer.—A good lotion for seborrhea of the scalp is the following

	gm or c c		
Mercuric chlorid		5	gr vii
Chloral hydrate	15		℥ ss
Perfumed spirit N F	30		℥ i
Water sufficient to make	500		O i

This can be used on the scalp and hair daily or every other day It is fully as effective as the resorcin solution, and much more agreeable to use In conjunction with such a lotion, either in case of oily hair or of dandruff, it is well to use on the scalp occasionally an ointment like the following

	gm or c c	
Salicylic acid	1 to 2	gr xx to xxx
Benzoic acid	3 to 4	gr xl to lx
Precipitated sulphur	3 to 4	gr xl to lx
Petrolatum	30	℥ i

This is applied occasionally—once in four or five days to once in eight or ten days—and is followed by shampoo in from thirty-six to forty-eight hours

REQUIREMENTS TO PRACTICE IN THE HAWAIIAN ISLANDS

To the Editor—Please inform me as to the requirements for license to practice in the Hawaiian Islands

Jois Morita Baltimore

Answer—To obtain a license in Hawaii the applicant must be a graduate of a reputable medical college having not less than four years of study, and must pass an examination in all the branches of the medical curriculum There is no reciprocity Examinations are held by appointment between the board and candidates The examination fee is $10 Address Dr W L Moore secretary, Board of Medical Examiners Boston Building Honolulu

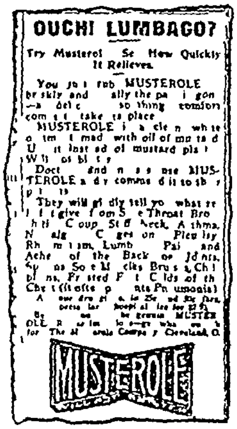
Idaho October Report

Dr Charles A Dettman, secretary of the Idaho State Board of Medical Examiners, reports the written examination held ment chemists reported that analysis "showed that the product was an alcoholic solution of oil of mustard, chloroform, opium and collodion" The therapeutic claims were declared by the government to be false and fraudulent and made knowingly and in reckless and wanton disregard of their truth or falsity The further claim made for the stuff that it was "invaluable in the household and nursery and no danger whatever can ensue from an overdose, as there are no poisonous ingredients in the compound" was declared false and misleading in view of the fact that the stuff contained chloroform and opium The defendant pleaded guilty and was fined $5—[*Notice of Judgment No 4353*]

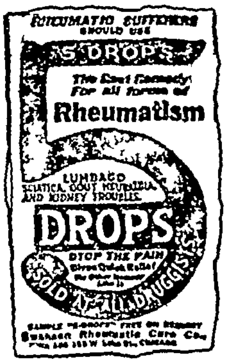


OUCH! LUMBAGO?
Try Musterol Se How Quickly It Relieves
MUSTEROLE

Musterole—This product, marketed by the Musterole Co, Cleveland, Ohio, was analyzed by the government chemists who reported that it was essentially a mixture of lard or some similar material with oil of mustard, menthol and camphor Claims made for the preparation were to the effect that it would cure *pneumonia, asthma, bronchitis, croup,* rheumatism and pleurisy and would prevent pneumonia These claims were declared false and fraudulent and applied knowingly, recklessly and wantonly The company would neither affirm nor deny the charge but was found guilty and fined $25 and costs—[*Notice of Judgment No 4358*]

Snyder's Bitters—The J H Snyder Medicine Co, Jonesboro, Ark, sold Snyder's Bitters under the claims that it contained 20 per cent alcohol, and would eradicate "Scrofula, Scrofulous Humors, Syphilitic Affections, Cancerous Humors, Ringworms Salt Rheum Catarrh and all diseases arising from an impure state or low condition of the blood" It was also said to be an "Unfailing Relief for Indigestion and all Diseases of the Liver and Kidneys" as well as a cure for malaria, to say nothing of being "an absolute panacea for all diseases and disorders of the female genital organs" These claims were declared false and fraudulent and applied knowingly, recklessly and wantonly The company pleaded guilty and was fined $10 and costs—[*Notice of Judgment No 4359*]

5 Drops—"5 Drops" was put on the market by the Swanson Rheumatic Cure Co, Chicago, Ill It was sold as a remedy for rheumatism, sciatica, asthma, hay fever, croup, la grippe, catarrh and malaria, as a preventive of germ diseases and as a cure for blood diseases, eczema scrofula and gastric ulcer as well as a preventive of *gallstones* The government chemists reported that analysis showed the stuff to consist of "a mixture of eucalyptol (or a eucalyptol-containing oil), camphor, safrol terpineol and eugenol (or an oil containing those ingredients, such as camphor oil)" The government declared the curative claims to be false and fraudulent and applied knowingly, recklessly and wantonly The company pleaded guilty and was fined $200 and costs—[*Notice of Judgment No 4372*]



RHEUMATIC SUFFERERS SHOULD USE
5 DROPS
The Best Remedy For all forms of
Rheumatism
LUMBAGO SCIATICA, GOUT, NEURALGIA AND KIDNEY TROUBLES
DROPS
STOP THE PAIN
SOLD AT ALL DRUGGISTS
Swanson Rheumatic Cure Co.

Dr Stuart's Specific Drops—Joseph W and Anna B House sold "Dr Stuart's Specific Drops" under the name Stuart Remedy Co, Detroit, Mich Claims made for the nostrum were that it was a cure for rheumatism and a positive specific for eczema and salt rheum and would drive all impurities out of the blood The government chemists reported that the preparation was essentially a mixture of camphor, alcohol, mercuric iodid and turpentine The curative claims were *declared false and fraudulent and* applied knowingly, recklessly and wantonly The defendants pleaded guilty and were fined $50—[*Notice of Judgment No 4368*]

Correspondence

Secret Remedies and Professional Responsibility

To the Editor—A man of great wealth and of social and business prominence in this community recently returned from an eastern visit during which he had occasion to consult a physician The physician, be it remarked, is a prominent educator, being dean of one of the most important medical schools of the country, a man of nation wide reputation, and of undoubted skill and ability as a practitioner of medicine He is also well known in the American Medical Association, of which he has long been a prominent and important Fellow, and is a vigorous enemy of secret remedies and a strong supporter of the Council on Pharmacy and Chemistry The above mentioned gentleman brought home with him a new and marvelous remedy which his physician had prescribed for him and which in an incredibly short time had cured his influenza and which, as grip was quite epidemic at home among his friends, he immediately recommended to several of them There is no greater joy to the average nonmedical person than to be able to advise a new remedy for one's friends' ailments, especially one so highly recommended, and as a result there was an immediate and large demand for this preparation, greatly to the profit of the local drug stores as well as of the manufacturer The remedy, a secret proprietary which has not been accepted by the Council and cannot be advertised in The Journal, is a preparation which has long been on the market is freely sampled to physicians in an attractive container and accompanied by the usual extravagant claims to cure many of the common diseases, and is recommended both for internal and external use This incident is related to show how sometimes our most ethical brethren help to boost the secret remedy

Burnside Foster, M D, St Paul

HEMATOXYLIN STAIN—DIAGNOSTIC VALUE OF VON PIRQUET REACTION

To the Editor—In the April, 1916 issue of the *Comptes rendus des séances et mémoires de la Société de biologie* Paris Triboneau Fichet and Dubriel describe a new hematoxylin stain—silver hemateinate The abstract I have gives no details as to its preparation

1 Please publish the detailed method *of preparing this stain*

2 Please give briefly the exact diagnostic value of the von Pirquet test

Robert Kilduffe, M D Chester, Pa

Answer—1 (*a*) Preparation of Silver Oxid In a carefully cleaned stoppered bottle dissolve 1 gm of silver nitrate in 100 c c cold distilled water Add to this quickly 50 c c of a 10 per cent aqueous solution of pure potassium hydroxid Shake well Let stand for one minute, decant from the heavy precipitate of silver oxid Wash this by decantation with four lots of 150 c c of distilled water, each (*b*) Preparation of Silver Hemateinate Dissolve 2 5 gm of French hematoxylin in 50 c c of absolute alcohol Pour this on the silver oxid Place the mixture in a long-necked flask and heat on the water bath *with occasional shaking* until the alcohol boils The liquid should be of a deep orange color Filter (*c*) Preparation of Silver Hemalum Staining Solution To one part of the silver hemateinate solution add twenty parts of a 5 per cent solution of potassium alum

2 It is not possible within the limits of a short answer to discuss satisfactorily the diagnostic value of von Pirquet's reaction The following is a partial list of the literature on the subject *published within the last two years*

REMOVAL OF BURNT POWDER FROM THE SKIN

To the Editor —Please give me the best treatment for removing burnt powder from the skin, the result of a pistol shot

W H Smith M D, Goldsboro N C

Answer —A reply to this question appeared in Queries and Minor Notes, The Journal, Nov 14, 1908, p 1716 In brief it was stated that if the patient is seen shortly after the accident, the gunpowder grains can be picked out readily Much of the powder can be removed by the same process later on, although this is tedious and difficult Watson and Keyes advocated the use of a cutaneous punch or trephine similar to that used for removing comedones The punch is placed over the powder mark and pressed down firmly Care should be taken not to enter the skin too deeply The small portion of skin which projects from the trephine can be snipped off and a soothing ointment applied Hydrogen peroxid is sometimes used, either full strength or three parts to one of glycerin Crile applies hydrogen peroxid until it has penetrated under the powder grains, the effervescence forcing them out of their bed

In case the powder marks are old they may be removed in the same manner as tattoo marks Methods of doing this are described by W A. Pusey, "Principles and Practice of Dermatology," in the chapter on 'Tattoo Marks and Powder Stains,' p 814, and also in Queries and Minor Notes The Journal, July 22, 1911, p 310, Sept. 12, 1912, p 895, and Jan 24, 1914, p 315

TREATMENT OF SEBORRHEA OF SCALP

To the Editor —In my books on skin diseases I find no lotions for seborrhea of the scalp except those containing resorcin This is so scarce and high priced that I cannot use it Could you give one or more formulas containing drugs that may be substituted for resorcin?

George G Smith M D, Chagrin Falls Ohio

Answer —A good lotion for seborrhea of the scalp is the following

	gm or c c		
Mercuric chlorid		5	gr vii
Chloral hydrate	15		℥ ss
Perfumed spirit N F	30		℥ i
Water sufficient to make	500		O i

This can be used on the scalp and hair daily or every other day It is fully as effective as the resorcin solution, and much more agreeable to use In conjunction with such a lotion, either in case of oily hair or of dandruff, it is well to use on the scalp occasionally an ointment like the following

	gm or c c	
Salicylic acid	1 to 2	gr xx to xxx
Benzoic acid	3 to 4	gr xl to lx
Precipitated sulphur	3 to 4	gr xl to lx
Petrolatum	30	℥ i

This is applied occasionally—once in four or five days to once in eight or ten days—and is followed by shampoo in from thirty-six to forty-eight hours

REQUIREMENTS TO PRACTICE IN THE HAWAIIAN ISLANDS

To the Editor —Please inform me as to the requirements for license to practice in the Hawaiian Islands

Jois Morita Baltimore

Answer —To obtain a license in Hawaii the applicant must be a graduate of a reputable medical college having not less than four years of study, and must pass an examination in all the branches of the medical curriculum There is no reciprocity Examinations are held by appointment between the board and candidates The examination fee is $10 Address Dr W L Moore, secretary, Board of Medical Examiners Boston Building, Honolulu

Book Notices

Focal Infection The Lane Medical Lectures By Frank Billings Sc D, M D Delivered Sept 20, 21, 22, 23 and 24 1915 Stanford University Medical School, San Francisco, Calif Cloth Price, $2 Pp 166 New York D Appleton & Co 1916

This volume contains the Lane lectures delivered by Dr Billings at the Stanford University Medical School in September, 1915

In the introduction Dr Billings traces in brief the history *of the development of* our knowledge of focal infections, noting especially the cooperative spirit between the clinicians and laboratory workers—the team work in which even nurses and patients took part—which made these investigations possible He shows how numerous research institutions were gradually drawn into the work, and with characteristic modesty disclaims the larger share of the credit for the investigations, naming himself as spokesman of those who took part in the work Those who know will say that he was the leader

In his first lecture, which is devoted to a general consideration of the subject, Dr Billings rapidly traces the growth of bacteriology and antiseptic and aseptic surgery He then takes up the etiology of focal infections, paying special attention to work on pyorrhea alveolaris It is interesting to note his position as to the importance of the endameba He says (p 6)

> Doubtless the endamebas play an important part in the occurrence of pyorrhea alveolaris and permit infection with the pyogenic bacteria The bacteria present in the infected areas are the important factors however in the causation of general infection from the focus

He then takes up other infections occurring in the mouth, throat, larynx and pharynx, naming the various organisms which usually inhabit these regions and produce diseases in them He considers also focal infections in the gastro-intestinal tract and its appendages, showing the relation of the popular idea of autointoxication to those infections He names, too, the organisms from the throat, nose and teeth producing lesions in the gastro-intestinal tract He considers the genito-urinary tract and then the general systemic effects of focal infections, the diagnosis of focal infection the various methods of dissemination of the organisms from the focus to the rest of the body, and finally the relation of infection to anaphylaxis

The second lecture concerns the streptococcus-pneumococcus group and the various transmutations which the members of this group undergo In this work the laboratory study was carried out chiefly by Dr Rosenow working under the direction of Dr Hektoen, and obtaining his clinical material largely from Dr Billings The work represents perhaps one of the most important studies of the last decade In this chapter are illustrations showing the transmutation of a hemolytic streptococcus from a case of scarlet fever into a *Streptococcus viridans* and into a pneumococcus Here Dr Billings quotes extensively from Rosenow s work on the elective localization of streptococci (The Journal, Nov 13, 1915, p 1687), and gives in detail the technic by which Dr Rosenow obtained his results

The third lecture concerns the acute diseases related to focal infection These diseases have always constituted one of the most puzzling problems of medicine Acute rheumatic fever, rheumatic endocarditis, myocarditis and pericarditis, chorea, the various gonococcal infections malignant endocarditis, nephritis, appendicitis, cholecystitis, gastric ulcer, pancreatitis, erythema nodosum, herpes, myelitis, thyroiditis and iridocyclitis are all shown to be frequently related to a focus of infection elsewhere in the body Credit is given to Poynton and Paine, the English investigators, whose early observations have been so brilliantly confirmed by American investigators When one contemplates the list of appalling diseases which have been taken from obscurity and made susceptible to scientific treatment, one begins to realize the greatness of the achievement In this chapter, too, are fifty-four illustrations showing the pathologic effects of the organisms, as well as the various phases of the organisms themselves

Naturally, the next lecture is devoted to the chronic diseases related to foci of infection, and every physician who has attempted to analyze and treat a chronic infectious arthritis, a chronic peptic ulcer or a chronic endocarditis will realize the great value of the investigations relating to these conditions The following statement is a short summary of one of the important findings (p 125)

> The focus of infection which undoubtedly causes the *Streptococcus viridans* bacteremia and chronic malignant endocarditis is often alveolar abscess. Of this we have had numerous clinical examples Coincident cultures from the alveolar abscess and from the blood have yielded strains of *Streptococcus viridans* When these nascent cultures were intravenously injected into animals, typical endocardial lesions resulted Doubtless a focus containing this streptococcus may be located in the tonsil or nasal sinus or elsewhere which may be the source of the cardiac infection

To many physicians the final lecture headed "Treatment" will be the most important The first part of the lecture is devoted to the prevention of focal infections The author then takes up the treatment of the resulting diseases, and in concise statements points out the necessary procedures The lecture concludes with a discussion of serum and vaccine therapy and the use of nonspecific protein injections

Many readers will, of course, be especially interested in Dr Billings' view on the use of vaccines in these conditions He states that it soon became apparent that estimations of the opsonic indexes were not an adequate guide to the effects of the vaccines Patients were then studied in two groups, one with vaccine and one without, and it was found that (p 154)

> The final result was quite as satisfactory without as with vaccine, in patients suffering with chronic infectious arthritis and acute rheumatism
>
> Patients suffering with chronic *Streptococcus viridans* endocarditis were not benefited by autogenous vaccines Indeed, I believe some of them were made distinctly worse when moderately large doses of vaccines were used

Dr Billings' concluding statement as to the therapeutic use of vaccines is a classic admonition which deserves a prominent place on the desk of every physician—in fact it might well be framed and pointed out to the ubiquitous detail man who foists his ultra-unscientific preparations on the unwilling physician (p 154)

> Based upon the work of Wright but disregardful of the principles developed by him therapeutic vaccination has progressed in this country into an irrational fad which is intensified and made degrading to the medical profession and harmful to the patients by commercial greed
>
> We are forgetful of the principles of medical practice of our fathers They recognized the influence of old age, exposure to extreme cold, poverty and poor nutrition physical and mental exhaustion faulty personal hygiene and other debility producing factors in the causation and also in the prolongation of infectious and other diseases They also recognized the necessity of the removal as far as possible of all these contributory etiologic factors in the management of the patient The modern vaccinationist pins his faith on the advertised specific virtues of stock vaccines, which he may employ in polyvalent form to insure a sure shot effect He believes vaccines will arouse specific defenses in the tissues of the patient in spite of all contributory etiologic factors of disease Therefore the rational diet proper baths passive and active exercise correction of personal uncleanliness and alcohol misuse are neglected The practitioner usually is ignorant of all laws of immunology It is this want of knowledge which makes him believe the ridiculous statements made by the manufacturers of vaccines
>
> Modern experimental investigation of the physiologic action of drugs has done much to restrict the abuse of drug therapy of the past So too, must the practitioner be made acquainted with what we know and do not know of immunology We must restrict the therapeutic use of bacterial antigens to those conditions which the known laws of immunity and scientific clinical experience have proved to be safe and of value

The final statement (p 157) is

> The mode of action of the nonspecific albumose antigens injected intravenously is not well understood Their use in acute and chronic infectious diseases affords a fruitful field of combined research by the immunologist and clinician

As readers of The Journal know, many new studies in this field are beginning to appear in medical literature

The book is slightly marred by a few minor typographical errors, but these, of course, will be caught in the next impression

The American Encyclopedia and Dictionary of Ophthalmology Edited by Casey A Wood, M D C M, D C L Professor of Ophthalmology and Head of Department, College of Medicine University of Illinois Volume 9—Institutions for the Blind to Lemotes Cloth Price $6 Pp 6419 to 7190 with illustrations Chicago Cleveland Press, 1916

This volume maintains the high standard of its predecessors There are so many articles of merit that it is impossible to enumerate them There is one, however, of such transcendent excellence as to demand special mention This is Dr Shastid's masterly monograph on the "Legal Relations of Ophthalmology" The interest of this article is by no means confined to the special branch of medicine with which it purports to deal In the introductory part the general question of technical evidence in this and other countries is treated, and the judicial organization is briefly but sufficiently explained This part of the article should be read by every medical man and every person interested in the question of expert testimony

The Medical Record Visiting List or Physicians' Diary for 1917 Leather Price, $1 50 (for 60 Patients a Week) New York William Wood & Co, 1916

The Physician s Visiting List (Lindsay & Blakiston's) for 1917 Leather Price $1 25 Philadelphia P Blakiston's Son & Co

These lists have been issued for 1917 with revised tables of dosages in apothecary and metric systems, based on the new pharmacopeia They contain the usual ruled pages for entering daily calls and visits, memorandums, consultations, obstetric engagements, vaccinations, deaths, addresses, and cash account Extra pages are devoted to tables of weights and measures, duration of pregnancy treatment of poisoning etc The books are nicely prepared in leather covers with a pocket for extra papers and a pencil in each Perhaps three fourths of the general practitioners of the country use these books as the first step in daily bookkeeping They are a valuable accessory to businesslike practice

NOTES ON ONE THOUSAND, THREE HUNDRED AMBULANCE CALLS IN NEW YORK

FREDERICK CHRISTOPHER, B S, M D
Assistant House Surgeon New York Hospital Second Surgical Division
New York

The character of work and the methods employed in an emergency ambulance service are of interest not only to the general practitioner, but perhaps more particularly to those who are contemplating engaging in such a service The fact that there has been no description of this type of work in recent years prompted the writing of the following brief account of a six months' service in New York

New York is divided into ambulance zones, the ambulance calls of each zone being answered by a given hospital, which acts in cooperation with the police department Each of these hospitals maintains from two to four ambulances and in case these are all out when a call comes in, it is referred to the hospital in an adjoining district

Any citizen who is sick or injured is entitled to the ambulance service An ambulance may be summoned (*a*) by asking a policeman, who is expected to satisfy himself that it is really needed before calling in from the signal box, or (*b*) by calling either police headquarters or the hospital directly giving one's own name and address and the nature of the case When a call is received in the latter way, a patrolman is dispatched at once from the nearest police station to the scene of the call Prisoners in the police stations are also treated by the nearest "ambulance surgeon"

The district of the New York Hospital includes the territory bounded by Forty-Second Street, Fourth Avenue, Fourteenth Street and the Hudson River The service is so arranged that on alternate days the second assistant house surgeon answers all first calls of the ambulance, and is on first call for patients coming to the accident room from 6 a m until the following 6 a m The second assistant house physician answers the second calls of the ambulance, and the third calls are taken by the other second assistant house surgeon who was on first call the preceding day, except during the six or nine hours he is off duty During the twenty-four hours on first call, the ambulance man averages about fifteen calls (twenty-three being a maximum) He is on duty for six months, and answers in this time from 1,200 to 1,400 calls

TABLE 1—CHARACTER OF CASES

Condition	Number
Lacerated wounds	269
Contusions and abrasions	171
Fractures 71, and possible fractures, 34	105
Alcoholism, acute and chronic	90
Gastro enteritis, etc	66
Syncope (fainting spells")	46
Hysteria	45
Dead on arrival	44
Epilepsy	35
Cardiac and cardiorenal cases	25
Tuberculosis	24
Diagnosis uncertain	24
Psychopathic cases	24
Arthritis and allied disorders	20
Labor	19
Pneumonia 11 and suspected pneumonia 8	19
Sprains ankle, 11 wrist 2, back 2	15
Incomplete abortion	14
Appendicitis 12 and suspected appendicitis 2	14
Hemiplegia 5 cerebral hemorrhage 6 and cerebral neoplasm 2	13
Dysmenorrhea	12
Burns	12
Gonorrhea chiefly epididymitis	10
Poisoning gas 3 strychnin, 1, iodin, 1, phenol (carbolic acid), 1, smoke 3	9
Heroinism	8
Salpingitis 4, metrorrhagia 2 endometritis 1, vulvovaginal abscess, 1	8
Dislocations shoulder, 4 thumb 1, little toe 1	6
Perforated gastric ulcer	5
Miscellaneous including convulsions 5 erysipelas 5, gunshot wounds 4, poliomyelitis 4 asthma 4 rectal abscess 4, carcinoma 3 cholelithiasis 2 tonsillitis 2, chorea 2, nephrolithiasis, 1 large uterine fibroid, 1, measles, 1 influenza, 1, vomiting of pregnancy, etc	155

The disposal of patients for whom the ambulance has been called is left to the discretion of the ambulance surgeon Either he may (*a*) treat the patient outside the hospital (in his home, the police station or elsewhere) as in the case of small lacerated wounds hysterical attacks, etc or (*b*) he may bring the patient to his own hospital where either he may treat the patient himself, or if the injury or disease is of a more serious nature the patient is admitted to the ward and seen by the house surgeon or physician, who in turn consults the attending surgeon or physician Patients with chronic conditions including pulmonary tuberculosis, acute venereal diseases and alcoholism, are taken directly to Bellevue, the large city hospital

The ambulance surgeon's bag contains a very practical outfit, including sterile instruments, gauze, needles, suture materials, and rubber tissue drains, razor, scalpel, mouth gag, stomach tube, sterile catheter, tracheotomy tube aromatic spirits of ammonia, usually administered by inhalation, tincture of iodin, soap solution, collodion, whisky, chloroform, alcohol and ether, ergot, baby cord, argyrol, nasal tampons, amyl nitrite pearls and a hypodermic outfit with solutions of the commoner drugs in rubber capped vials In the ambulance are kept padded splints of various sizes, bandages, boric ointment and sodium bicarbonate solution

The character of the cases is quite variable, and may best be understood by reference to Table 1, which shows the diagnoses made, some of which, however, proved to be incorrect The ambulance man is expected to make a diagnosis in the minimum of time, his chief concern being, "Is the patient's condition serious enough to warrant his being taken to the hospital?"

The lacerated wounds were chiefly of the scalp, and the majority of these patients were alcoholic, the injuries being sustained principally in falls or in fights, although there were many exceptional cases, as one of a patient who was struck on the head by a bolt which fell several stories from a structural steel work Street accidents, particularly those due to automobiles, accounted for a large number Fourteen of the 269 cases were stab wounds of varying extent, from a wound which laid wide the cheek, to multiple futile hacks with a penknife The severest lacerated wounds seen were in the cases of a longshoreman whose chest was torn through to the pleura and of a boy of 9 who had been run over by a heavy motor truck The smaller wounds were treated by tincture of iodin, a few horsehair sutures and a sterile dressing, and the patients were referred to a hospital for further treatment The more severely injured were brought directly to the hospital

In the class of cases under the heading "contusions and abrasions," the *chief interest lay in the responsibility* of excluding fractures or possible fractures

The fractures and possible fractures comprised an interesting group whose variety is indicated by Table 2

In the cases of fractures of the long bones, the clothing was rarely cut away, but a splint of adequate length (from foot to axilla in cases of fractured femur) was carefully bandaged on outside the clothing before the patient was moved A considerable number of the fractures were set and put up in molded plaster-of-Paris splints at the hospital by the ambulance surgeon himself In compound fractures an attempt was always made to place sterile gauze over the wound before applying the splint Two of the severest cases of this class were an attempted *suicide in front of a subway train in which* the patient sustained a compound fracture of the leg, and the other a "jitney-bus" crash in which the two patients sustained a compound fracture at the shoulder and a compound fracture of the leg, respectively The cases classed as "possible fractures" included those in which the possibility of fracture could not be excluded In these first-aid treatment should be identical with that of actual fractures

The alcoholics presented an interesting but uninspiring group Most of them were chronic alcoholics, the classical "bum" of common parlance, worthless derelicts with shaking hands, without jobs, whose beds were the park benches and whose blankets were newspapers Those with delirium tremens varied from the harmless "rat hunter" to those violent ones whom only the policeman's "nippers" could subdue The acute alcoholic coma, which caused the friends or bystanders to think the patient on the verge of death, was treated by having the extremities firmly held by the strongest persons around (the policemen) and by holding a large piece of gauze saturated with aromatic spirit of ammonia tightly over the nose and mouth The result was generally startling, and after a few emphatic remarks the patient would get up and walk home An ambulance service tends to give one an alcoholic point of view, and the temptation to forget that the alcoholic may suffer from other diseases as much as any one else is the ever-present danger of the ambulance surgeon I shall not forget one case of a bedraggled woman found in the street at 3 a m, whom I thought drunk, and took to the police station I attempted to revive her by compelling her to inhale the usual aromatic spirit of ammonia, but she died within ten minutes after her arrival This was a lesson not to be forgotten

TABLE 2—FRACTURES AND POSSIBLE FRACTURES

	Number
(*a*) Fractures	
Humerus	3
Clavicle	2
Skull	9
Colles	5
Patella	2
Nose	4
Fibula	3
Femur	3
Tibia	6
Radius and ulna	1
Jaw	3
Vertebra	1
Sacrum	1
Small bones of foot	4
Ankle	3
Compound including arms, legs, fingers etc	17
Miscellaneous	4
	71
(*b*) Possible Fractures	
Skull	14
Ribs	8
Small bones of foot	5
Vertebra	4
Ankle etc	3
	34

The group classed as hysteria comprised patients who best were calculated to try one's patience and whose treatment, moreover, was the most difficult of any of the ambulance patients. The subjects were chiefly young and emotional girls engaged in the intensive painstaking work of clothing manufacture, in which they seem constantly to be subjected to a high pressure to increase their output of work and not uncommonly are antagonized by the hectoring of selfish supervisors. The patient is generally found surrounded by a group of excited girls whose often frantic efforts to revive or to quiet her generally aggravate her condition. She may be almost rigid and anesthetic, or may be crying wildly. Tact, a few comforting words or the suggestion of a new train of ideas occasionally suffice to bring the patient back to normal condition. More commonly the best results seem to be obtained by refraining from sympathy, of which the patient probably has had generous measure before the physician has arrived, and by employing harsh vigorous words, or, as a last resort, forcibly compelling the patient to inhale aromatic spirit of ammonia. This rarely fails to bring about indignation—and a cure.

In the forty-four cases in which the patient was found dead on arrival, no attempt was made to assign a cause of death, this being a duty of the coroner's physician. The ambulance man has merely to pronounce the patient dead. The causes were often apparent, however—numerous cardiac failures, suicides chiefly by means of illuminating gas, falls from high buildings, and in one case each revolver bullet, elevator accident, and a wagon wheel passing over the head of the patient (a boy).

Several desperate cases of pulmonary edema were seen. By the administration of atropin and morphin it was usually possible to get these patients to the hospital.

No deliveries were made on ambulance calls. Patients in labor were taken to a hospital as rapidly as possible. When, as was frequently the case, the baby was born by the time the physician arrived, the cord was cut, the placenta expressed if necessary, and the patient was invariably offered the opportunity of going with her baby to the hospital.

Though there are only eight cases of heroinism listed above, not a few of the other patients were drug habitues. These patients never told where they obtained the drugs but almost invariably attributed the acquisition of their habit to "bad company."

There were a number of major surgical emergencies. Three perforated gastric ulcers were recognized. In one of four days' standing, with general peritonitis, the diagnosis was missed, while in another case in which the diagnosis of perforated gastric ulcer was made necropsy a few days later showed an acute hemorrhagic pancreatitis. There were a number of cases of acute appendicitis, two cases of acute cholecystitis, two cases of ruptured ectopic gestation and one of intestinal obstruction.

The four dislocated shoulders were successfully reduced on the ambulance calls. The patients with erysipelas were taken to Bellevue Hospital, and the board of health was notified of the discovery of cases of contagious diseases.

The ambulance service brings the physician into all kinds of places, from the Eleventh Avenue saloon fights to the Waldorf, from accidents in the crowded shopping districts to the squalor of the most crowded tenements, into the holds of ships, up in the iron framework of new buildings, behind the scenes at the theaters and sometimes to spectacular fires. On one occasion I was given rubber boots and lowered in an iron bucket down a concrete shaft to the great Catskills aqueduct nearly 300 feet below Broadway. For two hours I was in a wreck in the entrance to a Pennsylvania Railroad tunnel while a heroic conductor gamely kept his nerve until the steel wreckage which held his foot fast had been cut away by the oxyacetylene flame. I have seen a blind man who had bled to death from a ruptured varicose vein while his friends looked on helplessly, and the touching efforts of a Frenchman stricken suddenly dumb by a cerebral hemorrhage, to write us of his condition. On one call an excited policeman rushed up saying 'Doc, this guy's taken iodin and gone mad." But energetic lavage and subsequent questioning revealed the fact that he had tried to frighten his mother-in-law by spilling the iodin on his shirt front. The most bizarre call occurred in the case of F. J. M., Oct. 30, 1916, who, while under the influence of alcohol, fell ten stories through an iron grating onto the upturned nozzle of an automatic sprinkler. The impact of his body not only turned on the sprinkler, but simultaneously sent in a call to the city fire department. The firemen rushed into the building with their fire hose and, finding no fire, turned the water on the unconscious man, thus reviving him much to his astonished indignation. This man recovered in spite of fractures of a humerus, tibia and several ribs, and multiple lacerations.

A word of genuine praise must be said of the police with whom my duties have associated me during the last six months. Their willingness to be of any service to the physician, their good nature and patience under the most trying circumstances, and their unfailing courage and faithful performance of their duties have aroused my sincerest admiration.

In conclusion, two well-tried rules which are applicable to ambulance surgeons might be suggested: never lose your temper, and play safe.

Medicolegal

Validity and Application of Law Against Deceptive Advertising

(State Board of Medical Examiners vs. Jordan (Wash.), 158 Pac. R. 982)

The Supreme Court of Washington reverses a judgment of the superior court which reversed an order of the board revoking the defendant's license. The complaint alleged "That the defendant is a licensed practitioner of medicine and surgery under the laws of the state of Washington, that he advertised his medical business in the Seattle *Daily Times* of Wednesday, Oct. 1, 1913, and in sundry other editions of said Seattle *Daily Times* during the latter part of 1913 and the year 1914, that such advertising of his medical business was such as intended or has a tendency to deceive the public or impose upon credulous or ignorant persons and so be harmful or injurious to public morals or safety, in which respect defendant has been guilty of unprofessional conduct." The supreme court says that this complaint was sufficient. The statute has wisely allowed the defendant a first hearing before brothers in his own science. To say that such persons, unacquainted with the law, must conduct these examinations or invite them with legal nicety will not do. This court so held even on misdemeanor for practicing without a license. The courts uphold the less technical practice. The defendant's rights were easily protected either by demand for particulars or by motion to make more definite. The case was not criminal by its nature. The legislature had an undoubted right to classify this proceeding, and it did so by providing that appeals from the board should stand for trial 'in all respects as ordinary civil actions, and like proceedings be had thereon.'

The portion of the statute more particularly involved in this case was that part of the section defining unprofessional conduct which includes 'All advertising of medical business which is intended or has a tendency to deceive the public or impose upon credulous or ignorant persons and so be harmful to public morals or safety." It was contended that there is an uncertainty in this subdivision, and that it furnishes no standard by which either board or court can determine what advertisement offends. But the statute enumerates seven things that constitute unprofessional conduct, and the one relating to advertisement could not well be made more specific. To describe in express terms a faulty advertisement is practically to instruct the defendant how to evade it, and as to the limitless variations in language, symbols and verbal or pictorial allurements no human ingenuity could possibly anticipate and forestall them. To the court there seems a happy reply on any basis to arguments of this sort. Under the Washington statute the defendant is not tried on the advertisement alone, but on the advertisement and his capacity, qualifications or actions to fulfil it The appeal to the superior court secures a trial de novo, or anew In such trial a proper line of proof is not only the advertisement, but also the competence of the defendent to do what he advertises he can do The issue then becomes like that in getting money by false pretenses, which no legislature has ever been required to define The crime is determined not from the representations alone, but from all the actions and circumstances in which intent can be gathered The Washington law has not prevented a practitioner from advertising cures or inviting the public to his healing, but only advertisements to beguile It attacks not mere unethical conduct, but wrongful conduct If from the testimony it appears that he either does not cure the diseases, never has cured them, cannot cure them, or does not know what they are, the law has then a right to say it is advertising to deceive It is not merely unethical, but immoral, to get money from the poor, the simple or the ignorant by advertising the cure of what is incurable, and the courts will call that incurable which the present stage of knowledge so pronounces Nor was it incumbent on the state to show whether actual harm had yet come to any one through this practitioner That is not material The state aims to protect the purse as well as the health from quacks, and the other burden, if cast on the board, would, through the many confusing and contributing influences on the health of patients, make proof exceptionally difficult Neither was the court impressed by some twenty witnesses testifying to the defendant's cures, nearly all the patients being uncertain what their ailments really had been

Illegal Practicing Without Charging Fees — Not Emergency Service

(People vs Vermilion (Calif) 158 Pac R 504)

The District Court of Appeal of California, Second District, affirms a conviction of the defendant of having practiced a system and mode of treating the sick and afflicted without possessing a certificate issued by the state board of medical examiners entitling him so to do The court says that it was contended that he could not be properly convicted unless it were shown that he charged a fee for his services, but the court thinks that this contention must be decided against him The statute under which the prosecution was had makes it unlawful for a person to practice any art of healing without having first obtained a certificate from the medical board, and the court thinks the act is intended to, and does, cover such practice whether the service is gratuitous or not However, it was shown in evidence by the defendant's own testimony that he had engaged in the practice of a healing art, styling himself a “chiropractic,” for a period of five years immediately preceding the date of his arrest It was shown that he maintained a regular office in a business building in the city of San Diego, and there was testimony showing that he had treated in a professional way three different patients who were suffering from bodily ills There was evidence also that in one case payment was offered and accepted by him in return for the services rendered The defendant admitted the receipt of this money, but declined to state whether he regularly made a charge for his services The fair inference from all the testimony, which the court thinks the jury was entitled to draw, was that he regularly practiced a healing art, and, furthermore, that he did so for remuneration Some contention was made that the service which the defendant rendered to persons described in the evidence was in the nature of emergency service not prohibited by the medical act There was no evidence tending to show that the services were of an emergency character, that is, services rendered by way of affording temporary relief until the services of a regular practitioner could be procured The persons who were thus treated were shown to have previously had the attention of physicians, and their ailments were more or less of a chronic sort, and that the services of the defendant were sought, to some extent at least, as a last resort and after other practitioners had failed to afford relief Treatment so rendered could not, in any sense, be classed under the head of “emergency service”

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION

Twenty Ninth Annual Meeting held at White Sulphur Springs W Va Dec 11 13 1916

The President, Dr Thomas S Cullen, Baltimore, in the Chair

Biochemistry of Topical Applications Use of Boric Acid in Septic Infections

Dr Edward H Ochsner, Chicago Osmosis is not dependent on the semipermeability of the membranes, but on the chemical affinity different substances have for each other Concentration of the solution is also an important determining factor Clinically, laboratory experiments can be duplicated by using solutions of boric acid and water as a wet dressing A saturated solution of boric acid when applied to the skin will invariably appear in the urine in appreciable quantities within an hour, and if a wet dressing is kept in place for a considerable time, the amount of boric acid which appears in the urine may rise as high as 0.2 per cent In order to be effective, boric acid must be used in saturated solution While boric acid does not destroy pathogenic bacteria, it greatly reduces their virulence Wet dressings of boric acid are much more effective in streptococcus, *Staphylococcus albus,* and *S citreus* infections than in any other type of infection In order, however, that boric acid may reach its maximum of efficiency, some other directions should be observed, such as absolute rest in bed, proper attention to elimination, relief of pain, if possible without the use of opiates, by the addition to the solution of from 10 to 33 per cent of 95 per cent alcohol, painting the inflamed area with 95 per cent phenol (carbolic acid) until it turns white, and then removing the excess of acid with alcohol, elevation of the extremity with the muscles surrounding the involved joint at equilibrium, incision only when there is macroscopic evidence of pus and after a certain degree of immunity has developed If incision becomes necessary, an Esmarch bandage should first be applied whenever possible, and then the incised wound should be swabbed with tincture of iodin before the Esmarch bandage is removed and the part should be manipulated as little as possible

Treatment of Fractures of the Femur, Especially in the Old

Dr George Tully Vaughan, Washington, D C I do not believe in operating in every case of fracture of the femur or in putting foreign material into the tissues, except when necessary For neck fractures, with impaction and good position, plaster of Paris is applied, with the limb in normal extension, with displacement of fragments, Whitman's extreme abduction and plaster, if this should fail to effect reduction, I use the open operation, and the use of a screw or other means should be considered For shaft fractures, when Buck's and other methods of extension are not indicated and open operation is decided on, several methods may be used, preferably exposure of the fragments and their coaptation in such a way as to maintain their position by an external splint In oblique fractures this can be done by the interlocking method, that is, inserting one of the sharp ended fragments into the medullary cavity of the other, in transverse fractures, by an intramedullary splint taken from the fractured bone If it is necessary to use metal, the plates and bands are preferred to wire, nails and screws For transverse fractures, I use Lane's plates, and for oblique ones the steel bands of Parham and Martin No weight should be borne for four months on a femur which has been fractured, and good functional results should not be expected sooner than from six to twelve months

Open Treatment of Certain Fractures of the Long Bones

Dr H Horace Grant, Louisville, Ky The advantage of directing the adjustment and fixation of the fragments in most fractures of long bones under the eye is so *positive* as to need only a safe and simple method for general adoption Badly apposed, as well as ununited fractures of the long bones demand undelayed treatment by the open method Fixation by absorbable ligatures requires as much or more manipulation as putting in plates, and wiring of the fragments accomplishes poor fixation with the drawback of the retained foreign body The Lane plate in skilled hands accomplishes, perhaps the best fixation, but carries the serious objection to the inexperienced of infection, and even when all seems to go well, later removal is often required If by a simple inexpensive and safe method of fixation, not even involving the broken surfaces, approximation can be maintained, it should become the ideal method

DISCUSSION

Dr W P Carr, Washington, D C I protest against the recommendation for operating so freely, and against the idea of fixing a long bone in alinement by means of screws, plates or bands There are very few cases of fracture of the femur that require any operation at all

Dr A A Law, Minneapolis The Maxwell-Ruth method of treatment is particularly applicable to fractures of the neck of the femur in old persons

Dr. Alexius McGlannan, Baltimore The essential point in the treatment of fracture of the femur is to reduce the fracture The manner in which we fix the limb is a matter of relative indifference, because the bad results in treating fractures of the neck of the femur are due to the fact that the fracture is not properly reduced It can be reduced by abduction, traction and inward rotation

Dr J M Mason, Birmingham, Ala With the assistance of the fluoroscopic table we have been able to determine immediately what we are accomplishing in reducing fractures

Dr E D Martin, New Orleans One of the most valuable adjuncts in the treatment of femur fractures in old persons is the use of the Hodgen splint. I can recall at least fifty cases in which we made use of this splint with gratifying results

Substitution of the Anal for the Vesical Sphincter in Certain Cases of Inoperable Vesicovaginal Fistulas

Dr Reuben Peterson, Ann Arbor, Mich The operative procedure of substituting the anal for the vesical sphincter was suggested by Jobert in 1836 and Berard in 1845 It was performed first by Maisonneuve in 1851 but his patient died There were seven such operations from 1871 to 1881, twenty-two from 1881 to 1891, seven from 1891 to 1901, and there have been three since Childbirth was given as the cause of the defects causing the incontinence in thirty-three of the forty-one cases In four cases, incontinence followed removal of the urethra and parts of the bladder for malignant disease Sloughing following typhoid and diphtheria, and a gunshot wound was the cause in one case each In ten cases there were vesicovaginorectal fistulas, while in thirteen cases the urethra was destroyed In all the cases, almost without exception, plastic operations had been tried but had failed The woman should have the privilege of choosing such an operation in place of repeated attempts at plastic repair with failure The procedure never will be an ideal operation but is preferable to allowing the woman to suffer from urinary incontinence even if intercourse is interdicted The primary mortality of the operation should be nil In only one instance in the forty-one cases was there a primary death, the first patient in the series, who died of septic phlebitis an avoidable accident today In only two cases was there primary union of the colpocleisis wound but the resulting fistulas heal readily under caustic applications In not a single case of the forty-one was there rectal irritation There was no diarrhea some patients even being constipated Usually the urine is held from one to five hours with one or more formed stools a day In twelve cases the women menstruated through the rectum In nine cases the menstruation ceased after the operation without apparent cause Ascending renal infection did not take place in any of the cases The only doubtful case is that of Rose, in which the patient died ten months after the operation from nephritis which necropsy showed was not due to the operative procedures

Cure of a Double Femoral Aneurysm by Proximal Occlusions with an Autoplastic Fascial Flap

Drs E G Jones and C E Waits, Atlanta, Ga We partially constricted the femoral with an autoplastic flap dissected up from Poupart's ligament for the purpose of treating two aneurysms in the thigh Twenty-six months after the operation the patient remained well, and there were no signs of the aneurysms Function in the leg remained normal, except for some numbness about the calf In order to discover if such a band would be dangerous from the standpoint of erosion and hemorrhage, and if, when so applied, there would be material danger of gangrene or loss of function, we treated the femoral twenty-four times in dogs with uniformly satisfactory results The partial occluding band results in gradual complete occlusion of the vessel Histologic examination from twelve to fourteen weeks after operation shows the fibrous band grafted about the circumference of the vessel

Traumatic Aneurysm of Temporal Artery

Dr J Shelton Horsley, Richmond, Va Since 1896, only five cases of traumatic aneurysm of the temporal artery and its branches have been reported, besides two of my own In neither of my cases was there any evidence of syphilis or other disease of the arteries One was in a youth, aged 19, who received an injury in the right temporal region while playing basket-ball This was immediately followed by a large hematoma which was partially absorbed, but resulted in a small pulsating aneurysm about one-half inch in diameter Operation was done seven months after the injury under local anesthesia, the sac being excised after the arteries were ligated The second case was in a boy, aged 9 years, with a somewhat similar history, being injured while wrestling This aneurysm formed in the temporal artery just above the zygoma It was excised under local anesthesia There was no recurrence in either case

Some Problems of Ureteral Surgery

Dr William R Jackson, Mobile Ala Injuries to the ureter during hysterectomy are more frequent than is perceived at the time of the operation Discovery of the injury is more often made several days after operation than at the time it is performed It often means the sacrifice of the kidney of that side, and sometimes the death of the patient It is better not to attempt to repair the ureter, if there is serious doubt of its accomplishment Even if the operator is an expert, attempts at repair frequently result disastrously Removal of the kidney would be better under such circumstances A kidney should not be removed to cure a leaking ureter until one is sure of the presence of a perfectly sound kidney on the opposite side It is frequently better to ligate the ureter doubly than to attempt to do an anastomosis Before ligating it is well to ascertain if a kidney is present on the other side

Ureter Stricture

Dr Guy L Hunner, Baltimore By far the greatest source of ureter stricture is some distant focus of infection The diagnosis is made on the history, the urine examination, and the physical findings I take definite issue with the prevailing opinion that dilatation of the kidney pelvis and ureter are due to infection While the experimental work of Barney and others may lead to the view that the infection per se results in dilatation, one must remember that an inflammatory ureter with its extremely narrow lumen is more than likely to become partially closed at one of its normally contracted points and thus cause back pressure Many of my patients with sterile urine and no history of previous infection have the dilated ureter and pelvis The ideal treatment for stricture of the ureter is by dilation from the vesicle approach In cases in which dilation cannot be accomplished by the vesicle approach I advise extraperitoneal exposure of the ureter and retrograde dilation This was done in eight of my first fifty cases with excellent results in six Two of my early patients failed to obtain complete relief probably because of insufficient dilation Two of my first fifty patients had resection of the ureter with implantation in the bladder

Cholecystitis With and Without Gallstones

Dr George A Hendon, Louisville Ky Of thirty cases stones were *present in eighteen, or 60 per cent* A history of stomach trouble existed in twenty-five, or 83 plus per cent Nine cases, or 30 per cent, were jaundiced at some period in the history of the complaint

Recurrence of Gallstones

Dr John B Deaver Philadelphia The failure to remove all the gallstones at the primary operation is the most potent cause of recurrence of symptoms This adds emphasis to the arguments which surgeons are continually bringing forth of the importance of early operation Kehr does not hesitate to lay much of the blame for recurrent gallstones on the medical man He points out that in long standing cases the gallducts become dilated, and stones are apt to lodge in the recesses, so that they cannot always be removed or even be detected at operation, and thus give rise to renewed attacks of cholelithiasis My experience, comprising practically 1,200 operations in the last six years for affections of the biliary passages convinces me that the appendix in turn, is the focus of infection for nearly all upper abdominal diseases It is hardly necessary to dwell on the importance of early removal of even a slightly troublesome appendix in order to avoid future trouble Disease of the biliary passages is essentially a surgical and not a medical proposition

Choice of Operative Procedure in Cancer of the Rectum and Pelvic Colon

Dr Charles H Mayo, Rochester, Minn In the five years preceding 1916, our total operability was 53 per cent but in the last three years it has risen to 71 8 per cent, indicating that a chance for cure is now being given to a larger percentage of patients with this otherwise hopeless condition than formerly Of 753 patients a radical operation was performed on 430, with a general operative mortality of 15 5 per cent Before 1910 the operative mortality was 17 8 per cent From 1910 to 1913 it was 17 7 per cent, the operability being 51 per cent In this earlier period a higher percentage of patients were seen late In 1913, 1914 and 1915 the mortality was reduced to 12 5 per cent the operability was raised to 71 8 per cent, and the operative efforts were more radical Of the number of patients operated on, none less than three years ago, one third lived three years or more, and 28 3 per cent lived five years or more The patient with no anal control and with the sigmoid loop eliminated is much better off with an abdominal than with a perineal anus If with loss of the anus the sigmoid loop can be retained, the control will be fair, excepting in case of loose bowel movements Gas, however, is not controlled While the union of resected intestine within the abdomen is not followed by stricture, that affected outside of the peritoneal-lined abdomen is practically always followed by stricture, and will usually necessitate some form of colostomy after much effort to maintain the lumen If by abdominal procedure the division of the bowel below the growth can be made at a point which will leave at least one-half inch or more of peritoneal covered rectum within the culdesac, and the area of the disease to be removed is not too great to prevent coaptation of the divided ends of the bowel, a tube resection can be done with preservation of the control of the anal outlet as a one stage procedure Cancer of the rectum and rectosigmoid which cannot be removed radically with the preservation of the peritoneal-covered distal bowel is best treated by abdominal exploration, permanent abdominal colostomy and a Kraske removal of all of the rectum at a period one week later—a two stage operation Cancer of the lower sigmoid extending nearly to the rectosigmoid is well treated by the Mikulicz method, separation of the mesentery and elevation of the diseased loop through the exploratory incision to a position above the abdomen

1 **Treatment of Tetanus**—Gibson's personal experience in the treatment of tetanus is limited to eight cases, three patients died while five survived Of these the first two fatal cases did not have the benefit of the more modern or radical methods, whereas the last six are characterized by having received antitoxin intraspinally Of these six patients so treated since 1907 only one died, a mortality of 17 per cent Gibson advises that antitoxin treatment be begun immediately on suspicion of tetanus developing rather than waiting for the classical symptoms It should be given first into the wound or region of the wound, say 1,500 units, intraspinally, without an anesthetic, unless the treatment of the wound calls for the administration of a general anesthetic, 5,000 to 20,000 units In the course of the first twenty-four hours, in addition to the above, 10,000 to 20,000 units should be administered intravenously in divided doses, say two or three Antitoxin intravenously from 5,000 to 15,000 units should be given the next day no matter whether the symptoms remit or increase On the third day if, notwithstanding the treatment, the patient's symptoms continue very severe or appear worse, the intraspinal treatment should be repeated If after this treatment the patient holds his own or improves the intraspinal injection need not be repeated but the daily injection of antitoxin intravenously should be given until obvious remission or cure results One of Gibson's patients received a total of 169,000 units

2 and 3 Abstracted in The Journal, June 17, 1916, pp 2031 and 2032

4 **Salvarsan in Tuberculosis and Syphilis**—A review of the literature leads Potter to say that the prompt employment of salvarsan or neosalvarsan is indicated in latent, chronic and moderately active tuberculosis, (*a*) as soon as the nature of an added infection is diagnosed *with reasonable probability* to be syphilis, (*b*) whenever the history, signs, or symptoms strongly suggest a *previous syphilitic infection, particularly* if such a patient is not improving on the usually successful hygienic and climatic treatment for tuberculosis, but (*c*) active tuberculosis, acute tuberculosis and diffuse miliary tuberculosis are usually definite contraindications to the use of these new arsenic preparations, although in both the first two mentioned groups there will be found many syphilitic patients on whom a small dose of salvarsan may well be tried and, unless followed by untoward effects, cautiously repeated in gradually increasing doses When tuberculosis infects or becomes active in a patient with secondary, tertiary or even latent syphilis, the careful employment of one of these drugs is also indicated The more active the tuberculosis, the smaller should be the initial dose, the slower its increase, the less frequent the interval, and the greater care and watch-

fulness required Tuberculin like focal reactions may follow their administration should be carefully watched for and if present the location intensity and character will frequently guide in the selection of the next appropriate dose or interval

5 **Intestinal Autointoxication**—The peculiarity of toxin or bacteria in certain cases of so called intestinal toxemia or bacteremia was studied by Brown in three cases of chronic eczema and urticaria one of pruritus two of so called bilious headache and one of choroiditis This study suggested that in the intestine certain substances are produced which in some instances are possessed of specific action associated with a hypersensitiveness to certain proteins not in themselves toxic but possibly capable of producing a reaction because of an acquired hypersensibility and that therapeutically a marked improvement in symptoms and even a complete cure may be brought about by the elimination of these substances from the dietary It is also suggested to Brown by a study of these cases that by giving these foods in gradually increasing amounts a marked increase in resistance may be produced That in certain cases at least the symptoms are better explained on the basis of a bacterial infection of intestinal origin rather than on that of a toxemia and that in various cutaneous lesions, testing the cutaneous sensibility by intradermal injection of various proteins is of real value in determining whether or not the condition may be due to certain toxic bases of intestinal origin derived from the decomposition of certain protein foods These reactions are apparently specific in character and therefore these tests of cutaneous hypersensitiveness to various proteins probably cannot be used as criteria of other conditions best interpreted as protein intoxications with manifestations elsewhere than in the skin

8 **Treatment of Fracture of Spine**—In every case of fracture of the spine with damage to the cord excepting only complete obliteration of the bony canal Sharpe says an early laminectomy is urgently indicated to relieve the cord of the damaging effects of bone pressure hemorrhage and edema and to give the nerve tissue the best possible chance for repair

9 **Etiology and Prevention of Tuberculosis**—For each 100 000 population White wants a hospital of 200 beds a dispensary and an open air school There should be fifteen nurses, of whom five are visiting social service nurses and four or five physicians Such an equipment might easily expand and include all public activities child welfare pneumonia, syphilis and other health and public welfare problems The expense should be borne as the educational expense is borne and demand made mandatory by state law Large centers of population would be looked on as but the multiplication of units of 100 000 and the equipment would be multiplied accordingly Each unit would be self-governing but centralized in some central governing board which would establish the uniformity of the work and the prevention of overlapping

11 **Diabetes Insipidus and Pituitary Body**—A tuberculous man suddenly developed diabetes insipidus about two years before his death which was due to pulmonary and laryngeal tuberculosis At the necropsy a peculiar change in the posterior lobe of the pituitary body was found The pituitary fossa was not much if at all enlarged but the posterior lobe (pars nervosa) was relatively enlarged in proportion to the anterior lobe (pars glandularis), in fact, almost completely enclosed the anterior lobe, and was of a yellowish-brownish color, the color appearing to spread right into the posterior wall of the pituitary fossa The substance of the anterior lobe presented the normal glandular structure, but the posterior lobe contained large clumps of large granular cells with small nuclei, which stain deeply with hematoxylin Their cytoplasm has a granular appearance and many of them take on the sudan III coloration well In others of these cells, which stain less well with sudan III the cytoplasm appears to be full of minute crystals, doubtless fatty acid crystals of some kind, and probably it was a transformation of the lipoid droplets into fatty acid crystals that caused these cells to take on the sudan III stain relatively badly Weber and Schmidt think that these cells, which are possibly [illegible] origin may be regarded as one kind of "compound granular cells" (*Kornchenzellen*), the presence of which in considerable numbers forms a feature in various [illegible] conditions of the central nervous system Doubtless the lipoid containing cells in question gave the posterior lobe [illegible] the pituitary body in the present case its [illegible] yellowish brownish pigmentation

22 **Diagnosis and Clinical Characteristics of Gout**—One should always be suspicious says Pratt, that an attack of acute febrile inflammation of the joints occurring after the age of 35 in a person who has never had a previous attack of rheumatic fever is not rheumatism, but gout Acute endocarditis which is such a common complication of rheumatic fever does not occur in gout Another aid to differential diagnosis is the frequent association of gout and chronic interstitial nephritis, and the rarity of acute rheumatism and chronic Bright's disease in the same person Some of the cases of polyarticular gout Pratt has studied have closely simulated rheumatism In one case the correct diagnosis was not made by the eight or ten physicians who had treated the patient during the twenty-seven years that he had suffered from recurrent attacks of gout All had regarded the disease as rheumatic fever Pratt did not feel sure of the diagnosis until he saw the swelling on his elbow, which presented the typical picture of a chronic gouty olecranon bursitis The prompt relief from pain produced by colchicum in gout *is so striking that many have asserted* that this drug is a specific in gout It is certainly an aid in diagnosis as colchicum does not have such a marked effect in relieving the pain in acute rheumatism or in other con*ditions which may be confounded with gout* Salicylates rarely have any marked effect in controlling the pain of acute gout The relief from the severe pain of gout by atophan is even more striking than that produced by colchicum Its value in diagnosis is probably less as it often

is of considerable aid in checking the pains of nongouty arthritis

23 **Anaphylactic Action of Grains on Respiratory Tract**—Turnbull demonstrates the cutaneous reaction produced by proteins of wheat, barley, oats, corn and rice, and the anaphylactic action of the proteins of these grains, especially wheat, on the respiratory tract He has taken wheat as a standard, on account of its frequent and common use in daily diet He has obtained reactions to wheat in 100 cases A series of cases giving wheat reactions were tested with yeast, in no case was the reaction obtained One would thus form the conclusion that the yeast which enters in the making of bread has no anaphylactic action A series of pollenosis cases showed skin reactions to grain as follows wheat 100 per cent, barley 66 per cent, oats 64 per cent, rice 82 per cent, corn 90 per cent On the other hand, not all grain cases showed skin reactions to pollen of trees and plants Many pollenosis patients who avoided bread and boiled cereals, and used as substitutes those high, dry heated prepared cereals, to which they were not sensitive, found their symptoms diminished Pollenosis cases were desensitized in less time when eating these prepared cereals to which they were not sensitive

28 **Studies of Stomach in Syphilis**—In a group of 600 cases of syphilis with strongly positive Wassermann reactions were found forty-four with prominent stomach symptoms, after excluding patients with hepatic cirrhosis, gumma of liver, nephritis and tabes In thirty-five cases no definite lesion of the stomach was proved, in nine actual syphilitic or coincident lesions were found (ulcer, gumma or cancer) Two cases were proved cancer at necropsy five patients had ulcer, syphilitic or coincident, two had syphilitic induration or gumma The results of treatment are usually prompt and striking, the majority improve, even patients with severe complications like stenosis, perforation and hemorrhage A good portion are cured, but a small group do badly in spite of thorough treatment Gummas and induration melt away, but scar tissue does not dissolve and some deformity usually persists in the cases with gastric lesions Gastric secretion may remain absent after symptoms have disappeared In the thirty-seven cases without definite stomach lesion sixteen (43 per cent.) are well, eighteen (48 per cent) improved and three (9 per cent) no better In seven cases with stomach lesions (omitting the two cancer cases) three (43 per cent) are well, and four (57 per cent) greatly improved

37 **Venous Pulse in Auricular Fibrillation**—The systolic and diastolic waves of the venous pulse of twenty-five clinical cases of auricular fibrillation, recorded by photographic methods, were studied by Niles and Wiggers Six types of systolic waves were found (1) an intensified impact wave, the most common and often the only characteristic feature, indicating vigorous ventricular action, (2) a peaked impact followed by a rapid systolic drop due to light pressure of the tambour, (3) the intra-auricular type of systolic variation, so-called from its resemblance to intra-auricular pressure curves found in animals, occurring in clinical cases only when ventricular systole is weak, (4) double systolic waves, attributed to a systolic tug of the ventricle on the auricles and large veins, (5) a systolic impact followed by a stasis wave, present when intravenous pressure is high, (6) a regurgitation wave composed of a steep rise continued into a systolic plateau with murmur vibrations superimposed The study showed (1) that tricuspid regurgitation, as indicated by the presence of regurgitation waves, is a rare accompaniment of auricular fibrillation, and (2) that the contrary opinion, arrived at by the frequent presence in polygraph tracings of ventricular types of waves, is due to the fact that the contour of intensified impact waves is distorted by polygraph levers so that they simulate regurgitation waves Recurrent diastolic waves were frequently present in the records Their relative size depended, to a considerable extent, on the pressure of the tambour There was no constant relation to similar waves in the recorded electrocardiogram, nor is it proved that they are indicative of a coarse type of fibrillation or an associated flutter

38 **Diastolic Waves of Venous Pulse**—The conviction has grown that finer and coarser types of auricular movement may be recognized by the amplitude of the diastolic waves of the electrocardiogram and venous pulse The investigation into the cause of these waves made by Wiggers and Niles has shown that this is not possible The large recurrent waves of the venous pulse, which may with more reason be regarded as related to the size of the auricular mechanical contractions on theoretical grounds, are also shown to be without differential value

41 **Action of Digitalis in Pneumonia**—In a series of 105 cases of pneumonia studied by Cohn and Jamieson they found that digitalis given by the mouth has an action on the heart because changes occurred in the auriculoventricular conduction time and in form of the T wave of the electrocardiogram just as they do in the nonfebrile heart This conclusion is strengthened by finding that the pulse rate in fibrillating and fluttering cases fell in the presence of fever, exactly as it does in nonfebrile cases The dose and the time required to produce these effects are given and are the same as in the nonfebrile cases The authors conclude that digitalis act during the febrile period of pneumonia It produces a beneficial possibly a life saving effect in cases of auricular irregularity (fibrillation and flutter)

42 **Control of Strychnin Convulsions**—The results obtain by Cutler and Alton in a human case and in animal exper ments lead them to believe that magnesium sulphate ma of use in controlling cases of poisoning by strychnin Th amount of magnesium sulphate to be used should follow t advice of Meltzer in tetanus cases, intraspinally 1 c c of 25 per cent solution to each 20 pounds of body weight adults, and one half the dose in young children Sho this not control the convulsions, a small amount of ether m be used In order to hasten the excretion of strychnin, - to 300 c c of salt solution should be given intravenously the event of the return of the convulsions, the intraspinal d may be repeated, always taking precautions to keep the h elevated Meltzer's apparatus for intrapharyngeal insuffla and a 2 5 per cent solution of calcium chlorid should alw be on hand in case of respiratory failure following an o dose of the magnesium salts

44 **Arteriosclerosis and Glomerulonephritis**—Diphth toxin, given in large doses intravenously, Bailey f produces in the kidneys of the rabbit a pronounced vasc and parenchymatous degeneration The former consists swelling and desquamation of the endothelial cells of

arterioles and small veins with the formation of fibrinous thrombi, a necrosis and thrombosis of the capillaries of the tufts with hemorrhage and the formation of fibrinous and hyaline masses, and in some of the affected glomeruli considerable collections of polymorphonuclear leukocytes

45 **Extirpation of Thymus in Guinea-Pig**—Extirpation of the thymus in the guinea pig produced no changes in Park s experiments because accessory lobes of thymus derived from the third pharyngeal pouch occurring in close association with the parathyroids from the third pouch were found in serial section of the cervical tissues of eleven out of fourteen guinea pigs and the author thinks that they probably would have been found in all fourteen but for a technical error The discovery of these accessory lobes makes it certain that the guinea pig is unsuitable material for complete thymectomy and probably complete extirpation of the thymus in this animal is rarely, if ever accomplished

46 **Pituitary Body and Renal Function**—Extracts of the pars intermedia and posterior lobe of the hypophysis, given by the mouth subcutaneously, or intravenously Motzfeldt says are able definitely to check artificially induced polyuria Extracts of the anterior lobe show a similar effect but only to a slight degree This antidiuretic effect is constant and is independent of (*a*) changes in blood pressure, (*b*) intestinal absorption, and (*c*) the vagi The effect is apparently prevented or delayed by division of the splanchnics and is diminished by division of the renal nerves near the hilus These facts tend to suggest that the antidiuretic action exerted by pituitary extracts on rabbits is caused by stimulation of the sympathetic nervous system and that the renal vasomotor system in this respect is of chief importance Clinically these conceptions bring the polyurias related to disorders of the nervous system and the polyurias of pituitary origin in closer contact

47 **Connective Tissue Cells**—By the tryptic digestion of cultures in vitro of avian and mammalian connective tissue, suspensions of individual, living cells have been obtained Their ability to phagocyte carmin and bacteria has been tested The great majority of them fail to take up either but a few large cells are able to do so They will ingest bacteria only when serum is present, that is, they require the interaction of opsonins There is good reason to suppose that the phagocyte cells are endothelial in nature Should they prove to be fibroblasts, like the other elements present the fact will remain that the phagocytic power of fibroblasts is practically negligible Their failure to ingest foreign matter in vivo is to be laid not to the obstacles offered by the solidity of the tissue they compose, but to an inherent lack of ability on their part The phagocytosis of blood pigment, bacteria etc, which takes place in granulation tissue in vivo is probably carried on wholly by endothelial cells and wandering cells

55 Small Contact Epidemic of Typhoid M F Boyd Iowa City Iowa—p 109
56 *Etiology of Acute Epidemic Poliomyelitis G Mathers Chicago—p 113

52 **Beta Hemolytic Streptococcus**—The throats of individuals who have had tonsillitis, Smillie says may harbor the beta hemolytic streptococcus for three or more months after acute symptoms of the disease have subsided This streptococcus is found in large numbers in the throats of a certain proportion of patients with sporadic tonsillitis (five of twenty studied) Epidemic tonsillitis, or septic sore throat, is therefore, not a disease due wholly to the drinking of contaminated milk The disease may exist not only in the epidemic but in the sporadic form Tonsillitis, epidemic and sporadic, due to the streptococcus of the beta hemolytic type, may be severe or moderate or even mild The beta streptococcus is frequently found in the throats of patients ill with acute scarlet fever and may remain for months in the purulent discharges in the cases complicated by otitis media, etc These facts explain how the discharges from a scarlet fever patient may contaminate a milk supply and produce a milk-borne epidemic, not of scarlet fever, but of septic sore throat

56 **Etiology of Acute Epidemic Poliomyelitis**—In a bacteriologic examination of fresh material from ten cases of acute poliomyelitis a peculiar polymorphic streptococcus-like organism has been isolated in nine instances in seven of which the growth has been pure Similar organisms have been demonstrated microscopically in the tissues of the central nervous system of these patients Cultures of this coccus injected into rabbits have produced paralysis of various groups of muscles and characteristic lesions in the central nervous system consisting of hyperemia and edema of the tissues with hemorrhages round cell perivascular infiltration and neurophagocytosis in the spinal cord especially in the gray substance similar in every detail to the changes considered characteristic of acute poliomyelitis in man This micrococcus has been recovered from the lesions in the inoculated rabbits by both cultural and microscopic methods

The artificial cultivation of the poliomyelitis coccus in an ascites fluid tissue medium under anaerobic conditions causes changes in the medium which cannot be differentiated from those previously described for cultures of the so-called virus of poliomyelitis Morphologically also, this bacterium when grown on the same mediums is similar to the virus, and in stained smears it appears in minute gram positive coccus-like bodies arranged in pairs groups and chains These minute forms disappear when the organism is cultivated in other mediums under aerobic conditions The morphologic, cultural and pathogenic characters of the poliomyelitis coccus thus far determined indicate that it is an important factor in the disease

Journal of Pharmacology and Experimental Therapeutics, Baltimore

December 1916 IX No 3

57 Role of Liver in Acute Polycythemia Effect of Shutting Off Arterial Blood Supply to Liver Reaction of Normal Animal to Epinephrin and Removal of Liver from Circulation P D Lamson Baltimore—p 129

62 *Effects of Drugs on Ileocolic Sphincter M Kuróda London—p 187
63 *Pharmacology of Ureter Action of Opium Alkaloids D I Macht Baltimore—p 197

62 **Effects of Drugs on Ileocolic Sphincter**—The effects of atropin, pilocarpin nicotin and cocain on the sphincter are very similar to those on the intestine in general Yet the innervation of the sphincter is entirely different from that of the intestine in which the vagus is the augmentor, the splanchnic the depressor nerve while in the sphincter the splanchnic is augmentor and no inhibitory nerve has been shown to exist The correspondence in the action of these drugs on parts which are so different, suggests strongly that the seat of their activity is not the nervous apparatus, but the muscular And this is strengthened by the fact that epinephrin has an action on the sphincter opposite from in the intestine in general, thus changing along with character of the nervous activity

63 **Pharmacology of Ureter**—Morphin and its alli alkaloids increase the contractions and produce a grea

is of considerable aid in checking the pains of nongouty arthritis

23 **Anaphylactic Action of Grains on Respiratory Tract**—Turnbull demonstrates the cutaneous reaction produced by proteins of wheat, barley, oats, corn and rice, and the anaphylactic action of the proteins of these grains, especially wheat, on the respiratory tract He has taken wheat as a standard, on account of its frequent and common use in daily diet He has obtained reactions to wheat in 100 cases A series of cases giving wheat reactions were tested with yeast, in no case was the reaction obtained One would thus form the conclusion that the yeast which enters in the making of bread has no anaphylactic action A series of pollenosis cases showed skin reactions to grain as follows wheat 100 per cent barley 66 per cent, oats 64 per cent, rice 82 per cent, corn 90 per cent On the other hand, not all grain cases showed skin reactions to pollen of trees and plants Many pollenosis patients who avoided bread and boiled cereals, and used as substitutes those high, dry heated prepared cereals, to which they were not sensitive, found their symptoms diminished Pollenosis cases were desensitized in less time when eating these prepared cereals to which they were not sensitive

47 **Phagocytic Power of Connective Tissue Cells F S Jones* and P Rous New York —p 189

37 **Venous Pulse in Auricular Fibrillation**—The systolic and diastolic waves of the venous pulse of twenty-five clinical cases of auricular fibrillation, recorded by photographic methods, were studied by Niles and Wiggers Six types of systolic waves were found (1) an intensified impact wave, the most common and often the only characteristic feature, indicating vigorous ventricular action, (2) a peaked impact followed by a rapid systolic drop due to light pressure of the tambour, (3) the intra-auricular type of systolic variation, so-called from its resemblance to intra-auricular pressure curves found in animals, occurring in clinical cases only when ventricular systole is weak, (4) double systolic waves, attributed to a systolic tug of the ventricle on the auricles and large veins, (5) a systolic impact followed by a stasis wave, present when intravenous pressure is high, (6) a regurgitation wave composed of a steep rise continued into a systolic plateau with murmur vibrations superimposed The study showed (1) that tricuspid regurgitation, as indicated by the presence of regurgitation waves, is a rare accompaniment of auricular fibrillation, and (2) that the contrary opinion, arrived at by the frequent presence in polygraph tracings of ventricular types of waves, is due to the fact that the contour of intensified impact waves is distorted by polygraph levers so that they simulate regurgitation waves Recurrent diastolic waves were frequently present in the records Their relative size depended, to a considerable extent, on the pressure of the tambour There was no constant relation to similar waves in the recorded electrocardiogram, nor is it proved that they are indicative of a coarse type of fibrillation or an associated flutter

38 **Diastolic Waves of Venous Pulse**—The conviction has grown that finer and coarser types of auricular movement may be recognized by the amplitude of the diastolic waves of the electrocardiogram and venous pulse The investigation into the cause of these waves made by Wiggers and Niles has shown that this is not possible The large recurrent waves of the venous pulse, which may with more reason be regarded as related to the size of the auricular mechanical contractions on theoretical grounds, are also shown to be without differential value

41 **Action of Digitalis in Pneumonia**—In a series of 105 cases of pneumonia studied by Cohn and Jameson they found that digitalis given by the mouth has an action on the heart, because changes occurred in the auriculoventricular conduction time and in form of the T wave of the electrocardiogram just as they do in the nonfebrile heart This conclusion is strengthened by finding that the pulse rate in fibrillating and fluttering cases fell in the presence of fever, exactly as it does in nonfebrile cases The dose and the time required to produce these effects are given and are the same as in the nonfebrile cases The authors conclude that digitalis acts during the febrile period of pneumonia It produces a beneficial, possibly a life saving effect in cases of auricular irregularity (fibrillation and flutter)

42 **Control of Strychnin Convulsions**—The results obtained by Cutler and Alton in a human case and in animal experiments lead them to believe that magnesium sulphate may be of use in controlling cases of poisoning by strychnin The amount of magnesium sulphate to be used should follow the advice of Meltzer in tetanus cases, intraspinally 1 c c of a 25 per cent solution to each 20 pounds of body weight in adults, and one half the dose in young children Should this not control the convulsions, a small amount of ether may be used In order to hasten the excretion of strychnin, 200 to 300 c c of salt solution should be given intravenously In the event of the return of the convulsions, the intraspinal dose may be repeated, always taking precautions to keep the head elevated Meltzer's apparatus for intrapharyngeal insufflation and a 2 5 per cent solution of calcium chlorid should always be on hand in case of respiratory failure following an overdose of the magnesium salts

44 **Arteriosclerosis and Glomerulonephritis**—Diphtheria toxin, given in large doses intravenously, Bailey found produces in the kidneys of the rabbit a pronounced vascular and parenchymatous degeneration The former consists of a swelling and desquamation of the endothelial cells of the

arterioles and small veins with the formation of fibrinous thrombi a necrosis and thrombosis of the capillaries of the tufts with hemorrhage and the formation of fibrinous and hyaline masses, and in some of the affected glomeruli, considerable collections of polymorphonuclear leukocytes

45 **Extirpation of Thymus in Guinea-Pig**—Extirpation of the thymus in the guinea-pig produced no changes in Park's experiments because accessory lobes of thymus derived from the third pharyngeal pouch, occurring in close association with the parathyroids from the third pouch, were found in serial section of the cervical tissues of eleven out of fourteen guinea pigs and the author thinks that they probably would have been found in all fourteen but for a technical error The discovery of these accessory lobes makes it certain that the guinea pig is unsuitable material for complete thymectomy and probably complete extirpation of the thymus in this animal is rarely, if ever accomplished

46 **Pituitary Body and Renal Function**—Extracts of the pars intermedia and posterior lobe of the hypophysis, given by the mouth subcutaneously, or intravenously Motzfeldt says, are able definitely to check artificially induced polyuria Extracts of the anterior lobe show a similar effect, but only to a slight degree This antidiuretic effect is constant, and is independent of (*a*) changes in blood pressure, (*b*) intestinal absorption and (*c*) the vagi The effect is apparently prevented or delayed by division of the splanchnics, and is diminished by division of the renal nerves near the hilus These facts tend to suggest that the antidiuretic action exerted by pituitary extracts on rabbits is caused by stimulation of the sympathetic nervous system and that the renal vasomotor system in this respect is of chief importance Clinically these conceptions bring the polyurias related to disorders of the nervous system and the polyurias of pituitary origin in closer contact

47 **Connective Tissue Cells**—By the tryptic digestion of cultures in vitro of avian and mammalian connective tissue, suspensions of individual, living cells have been obtained Their ability to phagocyte carmin and bacteria has been tested The great majority of them fail to take up either, but a few large cells are able to do so They will ingest bacteria only when serum is present, that is, they require the interaction of opsonins There is good reason to suppose that the phagocyte cells are endothelial in nature Should they prove to be fibroblasts, like the other elements present, the fact will remain that the phagocytic power of fibroblasts is practically negligible Their failure to ingest foreign matter in vivo is to be laid not to the obstacles offered by the solidity of the tissue they compose, but to an inherent lack of ability on their part The phagocytosis of blood pigment, bacteria, etc, which takes place in granulation tissue in vivo is probably carried on wholly by endothelial cells and wandering cells

55 Small Contact Epidemic of Typhoid M F Boyd Iowa City, Iowa—p 109
56 *Etiology of Acute Epidemic Poliomyelitis G Mathers, Chicago—p 113

52 **Beta Hemolytic Streptococcus**—The throats of individuals who have had tonsillitis, Smillie says may harbor the beta hemolytic streptococcus for three or more months after acute symptoms of the disease have subsided This streptococcus is found in large numbers in the throats of a certain proportion of patients with sporadic tonsillitis (five of twenty studied) Epidemic tonsillitis, or septic sore throat, is therefore, not a disease due wholly to the drinking of contaminated milk The disease may exist not only in the epidemic but in the sporadic form Tonsillitis, epidemic and sporadic due to the streptococcus of the beta hemolytic type, may be severe or moderate, or even mild The beta streptococcus is frequently found in the throats of patients ill with acute scarlet fever and may remain for months in the purulent discharges in the cases complicated by otitis media, etc These facts explain how the discharges from a scarlet fever patient may contaminate a milk supply and produce a milk-borne epidemic, not of scarlet fever but of septic sore throat

56 **Etiology of Acute Epidemic Poliomyelitis**—In a bacteriologic examination of fresh material from ten cases of acute poliomyelitis a peculiar polymorphic streptococcus-like organism has been isolated in nine instances in seven of which the growth has been pure Similar organisms have been demonstrated microscopically in the tissues of the central nervous system of these patients Cultures of this coccus injected into rabbits have produced paralysis of various groups of muscles and characteristic lesions in the central nervous system consisting of hyperemia and edema of the tissues with hemorrhages, round cell perivascular infiltration and neurophagocytosis in the spinal cord, especially in the gray substance similar in every detail to the changes considered characteristic of acute poliomyelitis in man This micrococcus has been recovered from the lesions in the inoculated rabbits by both cultural and microscopic methods

The artificial cultivation of the poliomyelitis coccus in an ascites fluid tissue medium under anaerobic conditions causes changes in the medium which cannot be differentiated from those previously described for cultures of the so-called virus of poliomyelitis Morphologically, also, this bacterium when grown on the same mediums is similar to the virus, and in stained smears it appears in minute gram-positive coccus-like bodies arranged in pairs groups and chains These minute forms disappear when the organism is cultivated in other mediums under aerobic conditions The morphologic, cultural and pathogenic characters of the poliomyelitis coccus thus far determined indicate that it is an important factor in the disease

63 *Pharmacology of Ureter Action of Opium Alkaloids D I Macht Baltimore—p 197

62 **Effects of Drugs on Ileocolic Sphincter**—The effects of atropin, pilocarpin, nicotin and cocain on the sphincter are very similar to those on the intestine in general Yet the innervation of the sphincter is entirely different from that of the intestine, in which the vagus is the augmentor, the splanchnic the depressor nerve, while in the sphincter the splanchnic is augmentor and no inhibitory nerve has been shown to exist The correspondence in the action of these drugs on parts which are so different, suggests strongly that the seat of their activity is not the nervous apparatus, but the muscular And this is strengthened by the fact that epinephrin has an action on the sphincter opposite from that in the intestine in general, thus changing along with the character of the nervous activity

63 **Pharmacology of Ureter**—Morphin and its allied alkaloids increase the contractions and produce a greater

tonicity of the ureter Papaverin and its allied alkaloids produce a slowing or total inhibition of the contractions and a relaxation of the tonus In pantopium (total opium alkaloids) and other combinations, the effect of the benzyl-isoquinolin alkaloids predominates In spasmodic conditions of the ureter (renal colic), Macht says, the employment of papaverin or total opium alkaloids is more rational than that of morphin alone The slight toxicity of papaverin, its tonus lowering power, and its local analgesic properties suggest its local application in spasmodic conditions of the ureter

2 How to Use Crutches to Prevent Primary Contraction Hagentorn—p 834
3 *Pseudotuberculoma Silicoticum of Lip C R Nitch—p 835
4 *Second Primary Growths in Remaining Breast After Amputation of Other for Carcinoma D Drew—p 836
5 *Organism Present in Blood of Patients Suffering from Trench Nephritis R L Thornley—p 836

3 **Pseudotuberculoma Silicoticum of Lip**—A man fell off his bicycle when riding along a dusty country road, cutting the mucous membrane on the buccal aspect of his lower lip Some road grit was ground into the wound Healing took place in about fourteen days The resulting scar was somewhat thickened, but underwent no further change until a swelling began to form in its center Four months later the submental glands became enlarged and tender The glandular enlargement combined with the deformity of the lip produced by the increasing size of the tumor, led the patient to consult his physician Palpation of the tumor through the skin conveyed an impression similar to that given by a preputial chancre A provisional diagnosis of an endothelioma or of a fibroma surrounding a foreign body was made The tumor, together with the mucous membrane covering it and a quarter of an inch of the surrounding tissues, was excised from the buccal aspect of the lip, and the submental glands were removed Healing was uneventful Microscopic examination showed that the lesion consisted of a congeries or a mosaic of giant celled systems and huge giant cells, hardly to be distinguished from those of tuberculosis, although no caseation was present No tubercle bacilli or other bacteria were discoverable in the lesion in microscopic sections In practically all the giant cells however, and elsewhere there were particles of silica, which stood brilliantly out when the sections were polarized That the material consisted chemically of silica was proved by its insolubility in boiling nitric acid

4 **Second Primary Growths in Remaining Breast After Amputation of Other for Carcinoma**—Drew says that in his experience it is extremely rare to find a second solitary growth developing in the remaining breast after the lapse of two or three years, the patient being in good health and careful examination failing to reveal any evidence of secondary deposits in any other region

5 **Organism Present in Blood of Patients Suffering from Trench Nephritis**—With one single exception, every one of twenty-seven cases of trench nephritis examined by Thornley has shown the presence of an identical coccus in the blood Examined under the highest powers, the organism is seen to be an extremely minute diplococcus with adjacent surfaces flattened against each other It is usually seen singly or in groups seldom in chains They are nonmotile have no capsules and do not stain It grows readily, on ordinary agar, as a fine growth not unlike *Micrococcus melitensis* It does not liquefy gelatin on which it grows readily It ferments glucose, lactose, mannite, sorbite and saccharose within forty-eight hours, but not dulcite There is no formation of gas in any of the sugars Agglutination tests performed against it with meningococcic and *M melitensis* antiserums were negative in a dilution of 1 in 10

12 Ocular Vertigo T E Harwood—p 1014
13 Case of Aneurysm at Termination of External Carotid Artery K F Bolt—p 1015
14 *Rare Congenital Malformation W F Stiell—p 1015

9 **Meningococcal Infection**—The case cited by Elliott presented the features of an acute febrile condition accompanied by a very definite exanthem, the acute symptoms ending by crisis on the sixth day of illness In reviewing the facts obtainable, Elliott is convinced that the patient had suffered from an infection by the meningococcus without involvement of the cerebrospinal system and that the case falls into the so-called septicemia class of cerebrospinal fever The patient had specific antibodies to the meningococcus in his serum Attempts were made to obtain the organism in culture from the nasopharynx, but they were unsuccessful

11 **Diffuse Myxochondroma of Long Bone**—A female, aged 65 years, for seven and a half years complained of slight discomfort in the upper part of the right thigh without swelling, so far as she was aware, till shortly before her admission to the hospital At that time there was a visible fullness of the upper third of the right thigh, which felt as if due to a hard nodular enlargement of the femur, in the neighborhood of the great trochanter Passive movements at the hip joint were not impaired, the temperature was normal the patient s past history was negative, there was no evident metastasis, and the general health was unaffected Her single complaint was the increasing discomfort, amounting at times to actual pain, in the upper part of the right thigh On the roentgenogram general enlargement of the upper third of the femur was evident, consisting of tissue less dense than the imperfect shell or case of compact bone It appeared to be a central sarcoma, causing expansion with thining of the compact bone for which the limb was disarticulated at the hip In commencing the operation an incision was first made into the tumor, when a hemorrhagic friable tissue escaped supporting the presumption that the condition being dealt with was as diagnosed

14 **Rare Congenital Malformation**—The condition is bilateral in Stiell s case The total length of the upper extremity from the tip of the coracoid process to the tip of the longest digit is 7 inches Muscular development is excellent The elbow joint itself is entirely absent, but this is compensated by an abnormally efficient range of movement at the shoulder joint, while the mobility at both the wrist and interscapulothoracic joints is quite pathologic The radius and the ulna are entirely absent and the carpus is represented solely by the unciform os magnum, trapezoid, and one quite abnormal bone, probably a glorified scaphoid The metacarpal bones of the thumb and index finger are absent, as also the corresponding digits to these bones The three existing digits are held in the semiflexed position chiefly by contraction of the flexor tendons There is no syndactylism The humerus is represented by a short stout bone about 4 inches in length which articulates with a very abnormal scapula at its upper end and directly with the freak carpus at its lower Notwithstanding the total absence of both the radius and ulna, there is a normal range of pronation and supination, provided apparently by an exaggerated rotatory movement of the head of the humerus in the glenoid fossa With the exception of the upper extremities the remainder of the skeleton is normal There is no trace of any mental impairment

21 *Sublingual Medication A P Murtz—p 582
22 *Pain Caused by Dilatation of Deep Veins of Thighs J R Keith—p 584

19 **Tendon Repair Without Actual Suture**—In following the treatment for accidental division of tendon without actual suture Stiell says it is essential that four important details should all be present at one and the same time 1 It is of the utmost importance that the injured finger should be maintained in a position of hyperextension for at least three

weeks 2 It is necessary that the actual skin cut should have fairly close approximation of its edges, or, at least, the laceration must not be too extensive to render good apposition possible by means of skin stitches only 3 It is inadvisable to employ any form of drainage whatever for two reasons first, because it tends to remove the very necessary and beneficial blood clot from between the ends of the divided tendon, and second, that it only provides one more possible entrance for micro-organisms 4 Absolute asepsis is essential, or at least asepsis as regards the tendon sheath itself If these four important points in the method of technic are strictly observed, and the tendon sheath remains aseptic, primary union will invariably occur between the divided ends of the tendon without any actual tendon suture whatever

21 **Sublingual Medication**—The sublingual method of medication is endorsed by Murtz, who has used it for twenty years He regards the sublingual space the place par excellence for the rapid transmission by absorption of crushed hypodermic tablets into the circulation

22 **Pain Caused by Dilatation of Deep Veins of Thighs**—A woman, 57 years of age, about two years ago, began to be troubled with pain and swelling in the thighs These symptoms gradually increased, being produced by walking or standing and relieved by lying down Always absent in the morning on rising, in about an hour afterward they invariably made their appearance On examination, no objective signs were found to indicate the pathology of the condition, but as speedy relief was afforded by the application of elastic support it was evident that the symptoms arose from dilatation of the deep veins of the thighs

29 Case of True Hermaphroditism C Walther—p 230

26 **Gangrene of the Uterus from Measures to Induce Abortion**—Mauclaire remarks that induced abortion is becoming so common that it is astonishing that serious complications are not more frequently observed as the surgical services are so invaded by patients with febrile postabortion complications He here describes with illustrations four already published cases of fatal gangrene from this cause, with necropsy A number of other cases are briefly mentioned, his conclusion being that operative measures offer the only chance for saving the patient, although the conditions are decidedly unfavorable, whether the gangrene is in the fundus or in the cervix

27 **Perforation of Uterus During Attempt to Induce Abortion**—Beckman warns that if the physician does not know the circumstances of the case, he may fail to recognize that a foreign body has penetrated through the uterine wall into the abdominal cavity It was a *laminaria* in one of the two cases described and a bougie in the other In this latter case the supposed pregnancy was nonexistent, he remarks that this is the forty-sixth case of the kind on record The prognosis depends in large measure on whether the woman confesses or conceals what she has been doing At the same time we must remember that women may insist that a foreign body has penetrated the uterus wall when this did not occur He has had such cases, suggestion and fear prompting the avowal The surgeon must not take literally all that the patient relates As a rule, the reverse circumstances prevail, the woman does not know what the midwife has done to her, or she dissembles It is sometimes possible to palpate the foreign body through the walls of the abdomen, the rectum or the vagina It may become encysted and feel like a tumor In the two cases reported there were no signs of peritonitis until the fourth or fifth day, beyond a few vague symptoms Beckman advises to leave the uterus if there are no signs of infection Vasten removed a bougie from the abdominal cavity at the third month of a pregnancy which progressed to term In one case on record the bougie was felt in the Douglas pouch four days after it had penetrated the wall of the six months' pregnant uterus, abortion followed twelve days later The sixteenth day after this the woman consented to a laparotomy The bougie then was found between the umbilicus and the costal arch

28 **Obstetrics in France and Germany**—This is mainly a historical sketch of the evolution of obstetrics in Europe and of the hygiene of gestation and of puericulture

October 1916 XIX No 10 pp 505 560

30 Antitoxin in Treatment and Prevention of Diphtheria and Rarity of Accidents Therefrom (Les accidents consecutifs aux reinjections de serum et les injections preventives de serum anti diphthérique) A Netter—p 505
31 *Severe Aplastic Anemia in Two Boys of Six and Three E Gorter (Leyden)—p 525
32 Myopathy with the Reaction of Myotony in Girl of Thirteen L Babonneix—p 532
33 The Mongolian Blue Spot in Chili and Brazil (La tache bleue mongolique a Santiago de Chili) L C Mackenna—p 535
à Sao Paulo) G Ferreira—p 536
34 Belgian Children (Enfants belges victimes de la barbarie allemande) J Comby—p 537

31 **Aplastic Anemia**—In both the cases described there seemed to be some unknown cause slowly paralyzing the bone marrow There was no hemolysis to speak of, as was evidenced by the lack of intense urobilinuria and of hemolytic substances The bone marrow was yellow and there was fatty degeneration of various organs, especially of the liver and heart, but there were no signs of infection as responsible for the syndrome, no endocarditis, in the one case in which necropsy was possible. The family was healthy and the child had never had any serious illness but had always been pale The pallor had increased suddenly about three weeks before death, and petechiae had developed with fever and vomiting

Bulletin de l'Académie de Médecine, Paris

December 5 1916 LXXVI No 48 pp 437 452

35 Frequency of 'Hippocrates Finger' among the Troops (Sur les rapports du psoriasis avec la tuberculose) Railliet—p 439
36 Peculiar Gravity of d'Herelle's Dysentery Bacillus (Sur de nouveaux bacilles dysenteriques) Capitan—p 440
37 Comparative Harmlessness of Surgical Pneumothorax (Sur l extraction des corps etrangers extrapulmonaires) P Bazy—p 441
38 *Experimental Inversion of Impulse for the Heart Beat (Production experimentale d extrasystoles ventriculaires retrogrades et de rythme inverse, par inversion de la conduction de l'excitation dans le cœur) J P Morat and Petzetakis—p 442
39 Concretions in Bladder after War Wounds of the Bladder (Des calculs vesicaux chez les blesses de la vessie) F Legueu—p 445
40 Shrapnel Ball Loose in Spinal Canal Extracted through Cauda Equina M Auvray—p 447

38 **Experimental Inversion of Impulse for Heart Beat**—Electric stimulation of points on the surface of the auricle induces extrasystoles in the ventricle, and Morat and Petzetakis have succeeded in inducing extrasystoles in the auricle by electric stimulation of numerous points on the surface of the ventricle They experimented on dogs that had had the spinal cord severed at about the seventh cervical vertebra, and succeeded in stimulating the ventricle until it contracted each time before the auricle, thus reversing the impulse They explain that a nonreversible phenomenon may be composed of factors, which in themselves are reversible, and this is evidently the case here

Paris Médical

December 2 1916 VI No 49 pp 469 512

41 *Reeducation of Disabled Soldiers (Reeducations fonctionnelle et professionelle) J Camus—p 470 (Reeducation fonctionnelle des amputes du membre superieur pour les travaux de cultivateurs) Nove Josserand and Bouget—p 479 (Methodes de reéducation professionnelle des amputes) Bourrillon—p 487 (Reeducation professionnelle d apres les varietes d impotences) A Nyns—p 493 (La mecanotherapie agricole) J Belot and Privat—p 498 (Les ecoles de réeducation professionnelle de l Union des colonies etrangères) J Camus—p 504

42 *Reeducation of the Blinded (Remarques sur la réeducation des aveugles) F Terrien —p 490
43 *Responsibility of the Training Schools for Disabled Soldiers in Case of Injury from Accident (La responsabilite des œuvres de reeducation des mutiles de guerre au point de vue des accidents) E Fontane —p 496
44 Roentgen Treatment of Muscular Retraction Four Cases M Mercier —p 509

41 **Reeducation of the Maimed**—This entire number is devoted to the reeducation of mutilated soldiers Camus discusses the role of the physician It is to him that all look to decide when and in what the disabled workman should be trained Camus discusses further the placing of the men after they are trained, perhaps placing together men crippled in legs and arms, their concerted work accomplishing more than either alone Nove-Josserand and Bouget give an illustrated description of devices in use to facilitate work on farms, showing how the stump of the arm can be utilized

42 **Reeducation of the Blinded**—Terrien urges that the blinded should be sent to their homes as soon as possible as they can get about much better in ways with which they are familiar A number of blinded soldiers are now usefully at work on farms, attending to the milking of the cows, digging potatoes, beets, etc,, thrashing and making brushes on rainy days It is indispensable for the blinded to learn to read and write the Braille characters, there are now 40 000 books or pamphlets with this type A printing set is now available which has the Braille character on one end and the ordinary letter on the other end The type is set up by any printer with the ordinary letters, but when the form is closed the printing is done from the other side, thus printing the Braille letters No other system for the blind has stood the test of time like the Braille characters

43 **Legal Responsibility of Training Schools for Injury from Accidents**—Fontane suggests that it might be well for the public and private organizations engaged in training the maimed and blinded to take out accident insurance policies to protect themselves in case of accidents to any of the men in their charge as legally they are responsible for injury the same as the proprietor of a factory

Presse Médicale, Paris

December 7 1916 XXIV No 68 pp 561 568

45 Bone Grafting in Treatment of Pseudarthrosis (Cure des pseudarthroses par la greffe osseuse) V Pauchet —p 561
46 Tuning Fork Test for Simulated Deafness (Epreuve des diapasons unissonants appliquee au diagnostic de la surdite unilaterale simulee) E Escat —p 562
47 *Tests of Reserve Force of the Heart (Epreuve d aptitude cardiaque a l effort.) C Lian —p 563

47 **Testing the Reserve Force of the Heart**—Lian declares that the mere counting of the pulse after a given physical exercise will reveal whether the heart can be depended on for extra effort or not His 250 tests, including fifty healthy persons, have amply confirmed that the pulse changes are a good index of the reserve force of the heart He gives illustrations of the exercises he has found most convenient and instructive for the purpose The first is gymnastic stepping in one place bending the knees, two steps a second This is kept up for a minute Then the patient stands still without speaking and the pulse is counted during the first quarter of each minute thereafter until the count is the same as before the exercise In the healthy this occurs in the third minute, with a weak heart five to seven minutes may be required for it even to approach the previous figure His second test is to have a weight of 11 pounds seized with both hands and carried above the head and then swung down between the parted and slightly flexed legs which are firmly planted This is repeated five or six times in the course of a minute, and the pulse is then counted as before

Progres Médical, Paris

November 20 1916 XXXI No 22 pp 213 222

48 *Hemiplegia Following Scarlet Fever L Lortat Jacob and R Oppenheim —p 213
49 *Traumatic Exophthalmic Goiter Leniez —p 215
50 Treatment of War Wounds of the Elbow (Traitement des plaies articulaires du coude dans les traumatismes de guerre) D de Fortunet —p 217
51 *Test for Picric Acid in the Blood in Factitious Jaundice L Tixier and A Bernard —p 218

December 5 No 23 pp 223 232

52 Symptoms from Contusion of Cervical Spine (Le syndrome d hypertension cephalo rachidienne consecutif aux contusions de la region cervicale de la colonne vertebrale) H Claude and H Meuriot —p 223
53 Relapses in Amebic Dysentery (Les reviviscences de la dysenterie amibienne) J Carles and Froussard —p 226
54 Shrapnel Ball in Hernia (Balle d obus enrobee par le grand epiploon et mobile dans un sac herniaire) L C Bailleul —p 228

48 **Postscarlatinal Hemiplegia**—The patient in the case described was a soldier who had had a seton wound in the neck three months before Comparing the symptoms with other cases of postscarlatinal paresis confirms the assumption that cerebral arteritis is responsible for the chronic infectious hemiplegia in such conditions

49 **Traumatic Exophthalmic Goiter**—Leniez reports three cases of typical exophthalmic goiter developing in two army officers and a private after being thrown from a horse or falling from a wagon Each had fallen on his head, and after intervals of one, two and three months symptoms of hyperthyroidism developed, more or less pronounced Leniez has encountered also a number of other cases in which trauma had been followed by some symptoms suggesting a tendency to hyperthyroidism consecutive to injury of the head The exophthalmos was never pronounced in any of these cases, but the expression of the eyes was peculiar

51 **Detection of Picric Acid in the Blood**—Fifteen drops of the blood are received in a test tube containing 3 c c of 0 95 per cent salt solution The tube is agitated two or three times in the course of an hour, and set aside for twenty-four hours Then 1 or 2 c c of the fluid surrounding the clot is taken up with a pipet and added to an equal volume of a 1 50 000 solution of methylene blue Shake vigorously and after an hour s contact add ten or fifteen drops of chloroform and agitate anew then allow to settle The chloroform becomes a deep green a bottle green if there is picric acid present otherwise the chloroform does not change its color, or becomes only slightly blue

Correspondenz-Blatt fur Schweizer Aerzte, Basel

December 9 1916 XLVI No 50 pp 1665 1696

55 *The Present Problems in Roentgen Treatment of Cancer M. Steiger —p 1665
56 Preparation of Rice Pericarp as Influencing Growth from Its Vitamin Content (Vitamin und Wachstum) F Stirnimann —p 1678
57 *Exfoliating Dermatitis in the Newly Born in Its Relation to Pemphigus A Wirz —p 1685

55 **Roentgen Treatment of Cancer**—Steiger declares that in his experience the Roentgen rays have proved their usefulness in treatment of myomas hemorrhagic climacteric uterine trouble tuberculous glands in the neck—avoiding disfiguring scars—in tuberculous peritonitis and for vulvar and anal pruritus For cancer he advocates surgical treatment but makes a practice of Roentgen exposures after every operation for cancer, and also in the inoperable cases Much progress will be realized he remarks, when manufacturers provide us with Roentgen tubes that will stand a second's tension of 200 000 volts instead of only 120 000 as now available Aluminum does not seem to be a heavy enough metal for filtering the rays He is now using a zinc filter 0 5 mm thick This holds back the soft rays in much larger measure than even 3 mm aluminum while it yields much more of the hard rays It has thus two great advantages over aluminum, it spares the skin better and penetrates better and deeper into the tissues than is possible with the aluminum filter The cancer was favorably influenced in about 30 per cent of his fifty malignant tumors, including twenty-six absolutely inoperable cases Three patients in this latter group have kept in good health since for nearly a year to date In thirty-four cases the Roentgen exposures were only for prophylactic purposes In this category is the case of a woman who had required several operations for a sarcoma of the abdominal wall, but has been free from recurrence during

the two years since the last operation In this interval she has passed through a twin pregnancy

57 **Exfoliating Dermatitis in Relation to Pemphigus**—Wirz cites literature showing an unmistakable connection between exfoliating dermatitis and pemphigus in infants and reports an additional convincing experience A 5-day old infant developed the exfoliating dermatitis and died No other case was known in the foundlings' home or in the hospital to which it was brought However, in both institutions several other infants and older children developed pemphigus not long afterward It seems as if the germ causing the exfoliating dermatitis in the infants induced pemphigus in the older children

Deutsche medizinische Wochenschrift, Berlin

68 History of the Medical Certificate System for Soldiers (Geschichte der Medizin in Koln Die Entwicklung des militararztlichen Zeugniswesens) Haberling —p 1456

58 **Tsetse Flies and Trypanosomes**—Teichmann presents the present status of our knowledge on this subject He declares that it seems to be established that the trypanosomes in question are unable to pass through their whole cycle of development unless they have access to tsetse flies If the latter could be exterminated, these trypanosomes would die off with them

60 **Kaolin Fails in Treatment of Dysentery**—This is Wiese's conclusion from his extensive experience The men took the kaolin with extreme repugnance and complained afterward of sensations of oppression in stomach or bowel or both He insisted on keeping up the kaolin treatment, notwithstanding these by effects, until he found that it sometimes caked into hard lumps and these lumps caused irritation and pain as they were passed along Sometimes the lumps were as large as a hen's egg and hard as a stone He then dropped the kaolin entirely, and obtained much better results with the ordinary treatment thorough evacuation of the bowels, repeated moderate doses of simple tincture of opium, rinsing out the intestines with epinephrin enemas supplemented by animal charcoal given by the mouth, sometimes associated with bismuth subgallate

63 **Spondylitis of the Cervical Vertebrae**—In one of the three cases of Rust's disease reported, the trouble was of rheumatic origin, in the others syphilis or deposits of urates were responsible The clinical picture was practically identical in all, and the diagnosis of tuberculous caries seemed certain until involvement of other joints in the first case suggested a subacute form of articular rheumatism, affecting at first exclusively the suboccipital vertebrae The acute articular rheumatism cleared up the diagnosis in the first case, confirmed by the absence of evidences of an inflammatory process in the spine on roentgenoscopy Hnatek could find only three analogous cases on record In all there was considerable wasting and debility A concomitant apical tuberculous process pointed further to tuberculosis Careful watch over the other joints finally revealed further encroachment of the rheumarthritis In Condray's case, differentiation was facilitated by the *rheumatism in* both parents and by the sudden onset *in* two days following exposure to cold, one bitter night, near a drafty window The article is to be continued

64 **Albuminuria in Troops on Active Service**—Engel has had the urine examined of every patient admitted to the surgical hospital in his charge, a total of 3,210 men Albumin was found in 13 per cent but never in large proportions

75 *Treatment of Pneumonia in the Light of the History of Medicine (Die Behandlung der Pneumonie im Lichte der Geschichte der *Medizin*) T *Neuburger —p 1195*

69 **Etiology of Acute Articular Rheumatism Still a Mystery**—Rolly here reports from Leipzig the results of extensive experience with large numbers of cases of acute articular rheumatism In 118 cases at the acme of the febrile stage he found the blood always sterile, inoculating 20 c c or more of the venous blood on fluid and solid culture media In 2 other cases the staphylococcus was found but this was presumably accidental contamination In another case a streptococcus was isolated, but the case proved to be a viridans sepsis and not rheumatism With *Streptococcus viridans* sepsis there is liable to be transient swelling of the joints He does not venture to say that all previously published accounts of bacteria found in acute articular rheumatism are based on errors of technic, but queries whether mixed infection might not have been responsible for the positive findings The presence of bacteria on the tonsils and not in the interior of the body is no evidence that these bacteria are responsible for the articular rheumatism He found tonsillitis in 59 out of his 1,450 patients with acute articular rheumatism, 54 had sore throat, 54, pains in the throat, 10 of the patients had a history of recurring sore throat, 2 had had the tonsils operated on, and in 2 there was suppuration in the tonsils at the time The tonsils were found enlarged and red in 88, in 58 only red, in 133 only enlarged, plugs were visible in the tonsils in 23 and the tonsils were coated in 23 Other parts of the throat were red or swollen or both in 283, there was conjunctivitis in 3 and the conjunctiva was red in 6, 4 had bronchitis, and 1 acute rhinitis The patients also told that they had been subject to coryza (8), to cough (15), hoarseness (2), ear trouble (3), disturbances in swallowing (10), gastro-intestinal trouble (21) dryness in the throat (2), and 3 had had furuncles These figures demonstrate that sore throat is the portal of entry for acute articular rheumatism in many cases as it is of other diseases (nephritis, etc) But it is evident that other affections of the throat and other organs must also be considered *in this respect In one of the patients* acute articular rheumatism developed for the first time three weeks after an operation on the nose

Rolly presents evidence further to disprove the assumption that acute articular rheumatism is an anaphylactic reaction This assumption cannot be upheld, he says, so long as it is impossible to induce in animals the joint disturbances, the mere fact that fever can be induced is not adequate proof that this is the explanation of the disease In this connection Rolly tabulates the serum sickness phenomena observed in 2,122 diphtheria cases at Leipzig, only 5 75 per cent of all showed any disturbance from injection of antitoxin A congenital or acquired special susceptibility to alien serum is thus quite exceptional He also points out that only 57 5 per cent of those showing any disturbance developed an exanthem, with or without fever, while 33 3 per cent. had merely a febrile reaction, only in 9.2 per cent were there any disturbances in the joints and these were limited to pains in over half. Thus in only 4.8 per cent of the 122 who showed the slightest disturbance from the antitoxin, was there any tendency to swelling of joints. These figures show the rarity of joint trouble in serum sickness, and hence render it extremely improbable that acute articular rheumatism can be produced by anaphylactic phenomena. But anaphylactic phenomena may occur in its course the same as in any infectious disease.

72. **The Therapeutic Importance of Parenteral Injection of Milk.**—In this communication from the army hospital at Posen, Dziembowski reports encouraging experiences with what he calls 'protein body therapy." He emphasizes that the field for therapeutic parenteral serum and albumin injections is being enlarged more and more as it has proved that in many specific parenteral methods of treating disease there is usually also a nonspecific factor. A colon bacillus or pyocyaneus vaccine may work in typhoid as well as a typhoid vaccine, deuteroalbumose in typhus, diphtheria and tetanus, and diphtheria antitoxin or simple horse serum in hemophilia, erysipelas and other dermatoses. The use of milk for the purpose seems particularly promising as this is a mixture of albumin which is derived from the organism itself and its composition is constant. He has treated about 100 patients with intramuscular injections of 5 c.c. of milk, boiled for ten minutes in a water bath. In a few hours afterward there is regularly a chill, of variable intensity, and a rise of temperature from 38 to 39 C. (102.2 F.). The fever may last for a few hours or into the next day, and sometimes there are palpitations, headache, lassitude and depression but these last only for a few hours. No injury of organs, heart or kidneys, was ever observed and except for a little painfulness at the point of the injection no other untoward by-effects. The number of leukocytes runs up to 15 000 or even higher within a few hours, the increase is greatest in the neutrophils and then in the large mononuclears, while the lymphocytes show little increase or a decline.

His experiences with the method were decidedly favorable, especially with septic war wounds in four cases of severe erysipelas, in tuberculous bone and joint disease, in three of actinomycosis, and in large numbers of fractures. In the surgical tuberculous cases, with one injection every four days, the process healed within a few weeks after it had been dragging along previously a most tedious course. In the fracture cases, consolidation occurred in certain cases in which there had been previously scant tendency thereto and a pseudarthrosis was feared or had already developed. Good effects were also realized when the milk was injected for its styptic power, aiding in arresting internal hemorrhage or bleeding from mucous membranes or from wounds. In psoriasis the effect was also highly satisfactory, reenforcing the local applications. In one case with extremely severe psoriasis the skin cleared up almost completely in a few weeks under the injection of 5 c.c. of milk twice a week supplemented by quartz-lamp exposures and tub baths.

73. **After-Treatment of Acute Kidney Disease.**—Robert describes the way in which he trained convalescents from nephritis so they could resume their duties at the front and stand the army fare and the weather vicissitudes and the various tests with which he estimated the earliest moment when this was possible.

74. **Demonstration that Spirochetes are Plants.**—Meirowsky reproduces sixty illustrations of spirochetes as published by different authors, all showing bunches in the course of the spirils or actual buds on a stem. Hubener and Reiter regarded these bunches as characteristic merely of the spirochete they recently found as the causal agent of Weil's disease, and hence they named their spirochete the *Spirochaeta nodosa*. But Meirowsky declares that these are buds and that they demonstrate beyond question that spirochetes belong to the vegetable kingdom as true lateral branches are never found on protozoa while they are characteristic of filamentous fungi. Meirowsky called attention in 1914 to these buds on spirochetes, but his findings were rejected or explained away by others. He insisted further that these buds when detached from the parent stem, correspond to Much's granula with tubercle bacilli, and this seems now to be definitely established. The spirochetes of syphilis and of Weil's disease, and the bacilli of tuberculosis and leprosy all pass through a granular phase in the course of their existence. This explains the positive results obtained by Hubener and Reiter and also by the Japanese in infecting guinea-pigs with the filtered virus containing no spirochetes, confirming Neisser's and others' positive inoculation of monkeys with filtered syphilis virus. In the granular form the virus is able to pass through the filter. Be this as it may, the fact of the plant nature of the spirochetes now seems to be settled beyond question, he declares, as Koch, Metchnikoff and others have always maintained.

75. **Pneumonia.**—This work reviews the treatment of pneumonia during the last century or two. It states that Broussais regarded local and general withdrawals of blood as the best treatment, using 100 000 leeches in his service during the year of 1819, and during his own last illness having venesection done six times and sixty leeches applied. In 1827, 33 000 000 leeches are said to have been imported into France. Traube in Germany continued this use of venesection and leeches, and in 1849 a physician who had not bled a certain pneumonia patient had to answer in court for this neglect after the death of the patient, but was acquitted. Skoda was about the first to venture to teach that in most cases venesection was if not harmful at least superfluous. He advocated it only when a robust patient was suffering from much dyspnea with bloody sputum. In 1852, Neuburger's professor at Bonn advised him to go to Vienna to continue his studies, saying "They are not venesecting there in pneumonia."

One's own observation he continues teaches the more favorable course of pneumonia when nothing is done and the case is left entirely to Nature. The pulse may rise and fall, and the fever drop with or without the sweats of the crisis. We understand better the nature of the crisis since we know more of immunology. The outcome depends firstly on the greater or less resisting power of the heart, hence the importance of the pulse in this disease and the danger of the disease for infants and the elderly, secondly, on the height of the fever, thirdly, on the involvement of the nervous system, the so-called cerebral erethism of the elderly, and, fourthly, on the extent of exudation in the lung. The patient may recover with most extensive infiltration and may succumb with involvement of only one lobe. The regularity of the cyclic course surpasses that of other diseases, and the earlier the crisis appears the better, as this shows good production of antibodies.

Our task is to watch over the disease uninfluenced by drugs or other measures, keeping the patient in bed and avoiding needless effort till the last trace of infiltration and of fever has vanished. As pneumonia in hard drinkers does better under opium this should be given to ward off delirium tremens. Any debilitating diarrhea must be corrected, and the heart action kept good with small doses of digitalis (0.5 gm. in twenty-four hours), caffein sodium salicylate (0.2 gm. three times a day), and subcutaneous doses of camphor, the work of the heart facilitated by expectorants and the strain from coughing reduced with narcotics, keeping up the strength with liquid or solid food, and, if the fever is very high two doses of phenacetin in the twenty-four hours, by the mouth or rectum, with ice to the head and cool compresses on the affected side of the chest or, if this does not help, with packs. Adults do not bear well repeated cool or even tepid full baths; young children seem to bear them better. As the crisis approaches or passes, the nervous system may be involved, the tongue trembling, the tendons twitching and delirium sets in. If this is not a complication from arteriosclerosis of the cerebral arteries, stimulants are indicated, brandy, camphor, mellow wine. The longer the physician practices, so that he can get a bird's eye view of his experiences the more distinctly he realizes that our medical measures are of incomparably small effect in comparison with the internal processes of the organism. Medical science seems to move in circles, but the circles are like the coils of a spiral, each one bringing us nearer to the truth.

76 **The Toxic Action of the Arsenic in Lead Projectiles**—Lewin has found that the lead and antimony alloy used in making shrapnel balls is liable to contain from 1 to 3 per cent arsenic, and he has been investigating the possible toxic action from a shrapnel ball in the tissues An ordinary ball weighing 10 gm, containing 8 per cent antimony with about 14 mg arsenic, was chopped into 100 pieces and submitted to the action of hydrochloric acid or olive oil The results showed that such balls in the stomach are not liable to prove toxic but, embedded in the tissues, the alkaline juices act on the projectile and release the arsenic But even here the arsenic would be carried away and harmlessly eliminated On the other hand, the danger from the lead is paramount and always serious The lead is comparatively soluble in the body juices and fats while it is retained and stored up in the nerves and brain and is liable to induce manifold symptoms

77 **Absorption of Air in the Stomach**—Ylppo experimented on himself, introducing given amounts of gas or air into his stomach He found that it was evidently absorbed by the stomach walls, the alveolar air promptly showing the effect Further tests established that carbon dioxid and oxygen diffused into the blood through the walls of the gastro-intestinal tract while common air did not diffuse and was passed along as flatus

78 **War Babies**—Tschirch reports statistics from Jena which show that the infants that have been born during the war average as well in weight as during peace times Also that lactation does not seem to be modified by the scarcity of fat and albumin in the food

79 **Gummas in the Heart**—The patient in the case described was a man of 44 and he presented the Adams-Stokes syndrome and also attacks like the petit mal of epilepsy, completely losing consciousness these brief attacks occurring forty or fifty times an hour, day and night, so that in the five weeks the man was in the hospital he had nearly 25,000 Toward the end the intermissions grew so short that the attacks were practically continuous No benefit was apparent from mercurial and iodid treatment and the condition was considered too precarious to attempt salvarsan At necropsy several gummatous nodules were found in the heart but the auricular-ventricular bundle showed merely small-cell infiltration between the muscle fibers and no gummatous changes The auricle beat three or four times to the ventricle s once but the regular ratio was preserved, the heart block not being complete The only case approaching this in respect to the frequency of the epileptiform seizures was one of Zong's with 200 in twenty-four hours, but in the present case there were 800 With the onset of the attack, the ventricle action seemed to be suspended completely for from five to forty-five seconds, indicating that the heart block had become total during this phase but partial conduction was soon restored again The arrest of the ventricle action suggests that a reflex from the heart shutting off the blood from the brain, was responsible for the attack. Disturbances of this character might retrogress under specific treatment, but the condition is generally too far advanced when the case reaches the physician If the assumption is correct that other fibers might vicariously conduct the impulse, even with actual heart block, then antisyphilitic measures might prove successful even in quite pronounced cases

80 **The Ventricle-Systole Wave of Electrocardiogram**—Gerhartz states that the final T peak occurs during the systolic phase of the heart action but does not necessarily end with it. Straub recently analyzed the electrocardiogram in a case of paroxysmal auricular tachycardia and found that the normal interval of 0 39 was reduced to 0.25 He regarded it as impossible for this abnormal shortening of the interval to be due to a more rapid course of the systolic contraction or even for it to parallel the latter This view is confirmed by the findings in a normal man described by Gerhartz In rest, the diagram shows a longer interval between the R and the T peaks but the T peak extends farther Immediately after physiologic exercise, the T peak begins earlier and ends before the corresponding end of the T peak at rest while the following interval is not much more than a third of the same interval in repose and the P peak is only about two thirds as long The systole is thus materially shortened under the influence of mild physiologic exercise It seems thus to be established that the T peak can change independently of the R or ventricle peak and not parallel the duration of the systole The shortening of the systole with paroxysmal tachycardia is thus merely an exaggeration of normal relations

81 **Arrest of Gastric Hemorrhage with Extract of Blood Platelets**—After a gastro-enterostomy the patient had profuse hemorrhage from an old and supposedly healed ulcer While the abdomen was open the blood platelet extract was injected into the stomach in a 10 per cent solution, the hemorrhage ceased at once and there has been no return during the month to date The danger of arousing an old healed ulcer should be borne in mind in operating on the stomach, and some of this extract might be injected or swallowed as a preventive

83 **The Endurance in Kidney Disease**—Geigel naturally discusses this subject from the standpoint of fitness for military service The quite chronic forms of interstitial nephritis and true contracted kidney, which have developed insidiously do not exclude army service unless there are acute attacks of parenchymatous inflammation Prophylactic vaccinations should be avoided with kidney affections of all kinds unless an epidemic threatens Not much endurance can be counted on when there has been pulmonary edema uremia or cerebral hemorrhage at any time, as also when the fundus of the eye shows changes or the blood pressure is 180 or over Garrison duties are permissible when the blood pressure is between 160 and 180 The rise in blood pressure under the influence of war conditions is not to be dreaded when the individual is young or middle aged, but arteriosclerotic contracted kidney excludes even light service

89 **Nerve Blocking in the Field**—Schmid has found local anesthesia of the greatest use for the wounded when the injured area is accessible, but when it is deep in the tissues

the nerve blocking technic is preferable and he is enthusiastic in his commendation of it With the paravertebral technic it is possible to induce analgesia for the entire trunk and neck For parasacral anesthesia he injects 2 c c of a 1 per cent solution of novocain and epinephrin into the sacral nerve as it emerges and runs along the sacrum The needle is introduced about 2 cm to one side of the sacrococcygeal joint This is repeated on each side. The second and fourth sacral nerves are injected under the guidance of the finger in the rectum, the needle feeling its way along the sacrum If the phrenic nerve is carefully avoided he thinks there is no danger from these nerve-blocking technics

95 **Lice in Transmission of Relapsing Fever**—The Journal mentioned on page 155 Töpfer s statements to the effect that while lice are an important agent in the transmission of relapsing fever yet it is not by their bites but only by their being crushed on the skin that the spirochetes find their way into erosions from scratching Prüssian's experience has confirmed this assumption in every respect, and it offers an explanation for the previously inexplicable immunity to relapsing fever often displayed by attendants and others with cleanly, hygienic habits

102 Atypical Variola, Two Cases (Atypische Blatternfalle) Wiener—p 1413

96 **Syphilitic Aorta Disease**—Korczynski reviews recent literature on this subject and reports data compiled in Bosnia and Herzegovina during the last two years At the Sarajevo hospital there were during this period 251 cases of disease of the cardiovascular apparatus, exclusive of pericarditis, and in nearly 22 per cent syphilis was present. Half of the fifty-four patients were between 40 and 50, but there was one of 15, one of 18, and two were between 20 and 30, with four between 60 and 65 Over 70 per cent were from cities The shortest interval between infection and the aorta affection was three years, from fifteen to thirty was the average Grau has reported a case developing forty-one years after infection The leukocyte picture was modified in nearly every case, the small lymphocytes being abnormally numerous This in itself suggests the syphilitic nature of the trouble

98 **Modification in the Blood After Vaccination Against Typhoid**—Labor found abnormally high eosinophil count in a number of men during an epidemic of scurvy Study of this eosinophilia demonstrated finally that it was a tardy phenomenon following vaccination against typhoid In ninety healthy men and wounded vaccinated against typhoid but who had not been given antitetanus serum he found no eosinophilia the first month it was present in 20 per cent the second month, in 57 per cent in the third month, in 43 per cent in the fourth with the maximum eosinophilia of 21 per cent in two of these cases By the sixth month no eosinophilia was evident, in the seventh month slight eosinophilia was apparent in a few and none after this The lymphocytosis of the first period gives way to this eosinophilia which persists an astonishingly long time No connection between it and the agglutinating property was evident. In two cases of typhoid occurring in the second and fifth month the eosinophils were much below the normal figure

101 **Typhus**—Fonyo's article was reviewed in these columns January 13, p 156 abstr 96

108 **Psoriasis from Emotional Stress**—Lutati has been impressed with the numbers of cases of psoriasis among the soldiers in Italy, the same as Gaucher in France It seems to develop after a nervous shock, a violent emotion or trauma but Lutati is convinced that this can occur only when there was already a possibly latent tendency to the disease

109 **Fever in Mastoiditis**—Bilancioni cites some typical cases to illustrate that fever is by no means a constant accompaniment of even very severe cases of mastoid disease, even in young children

110 **Pathogenesis of Femoral Hernia**—Miliani reports some cases of femoral hernia which sustain T Turner's views as to the mechanism of the development of this form of hernia, as published in 1914

111 **Emergency Hemostasis for War Wounds**—Among the measures advocated, Sacco calls attention in particular to immediate suture of the skin as a means to control bleeding from a wound made by bullet or shrapnel ball, without wasting time in seeking for the exact source of the lesion He found that the hemorrhage promptly stopped as soon as the skin wound was sutured In the cases described the wounds had been dressed on the firing line, but the oozing of blood kept up until the skin was sutured

114 **Ocular Anomalies that Lead to Blindness**—Bilancioni cites a number of eminent scientists in different lands who lost their eyesight, saying that cataract does not seem to be more frequent among scientists and professional men than among other classes of the population, but glaucoma, detachment of the retina sclerochoroiditis (especially in myopic eyes) retinal hemorrhages and other intra-ocular disturbances in circulation occur in far larger proportion among persons of a studious tendency than among others He says that not a few professors in the universities of Italy have become blind from optic neuritis, retinal hemorrhage or detachment of the retina

118 **Idiopathic Perirenal Hematoma**—In Hansen's patient, a secundipara of 35, the hematoma entirely encircled the kidney, but no cause for it could be detected on direct inspection of the kidney, pelvis or suprarenals Recovery was soon complete after draining the blood away In some of the twenty-three cases on record nephrectomy was done, in others the hematoma was merely drained All died of the seven not given operative treatment, and four of the sixteen operated on The diagnosis was made beforehand in only three cases

119 **Experimental Bile Peritonitis without Perforation of Biliary Passages**—Blad gives the details here of his work on rabbits and twenty dogs He thus demonstrated that colloids are unable to pass through the gallbladder walls, but that crystalloids pass readily through them Hence if the gallbladder contents become digested by ferments in connection with bacterial action, the bile can pass readily through the walls of the biliary apparatus without perforation He explains that the ferments involved are probably derived from the pancreas

127 *Herpes Zoster (Motoriske og sensible forstyrrelser ved Herpes zoster) V Magnus —p 1612

122 **Drainage with Peritonitis**—Barth reviews the literature, 1912 to 1915 on the subject of draining the peritoneum in peritonitis The cases of appendicitis in his own experience (Schilling's service, Christiania) accompanied by peritonitis are tabulated, the sixteen one-page tables thus giving an oversight of the outcome with and without drainage and with and without rinsing Statistics from other clinics are cited, the length of stay in the hospital being also regarded The summary conclusion from the whole is that the outcome is better when diffuse peritonitis is treated with drainage, but localized peritonitis does not seem to require it, the results being practically the same whether drains are used or not

123 **Sacral Anesthesia for Genito-Anal Pruritus**—Holland remarks that in cases of genital or anal pruritus rebellious to all other measures, great benefit can sometimes be obtained from temporary anesthetization of the region The itching and the scratching keep up a vicious circle, let this be broken once and conditions may right themselves As a comparatively simple and extremely effectual measure for the purpose, he commends sacral injection of a weak anesthetic solution He describes six typical cases of pruritus of the genito-anal region in men between 30 and 66 The itching was alleviated by one injection and subsided entirely after a second or third There was complicating eczema in some of the cases, and the pruritus was so intense in one case that sleep was impossible This patient had obtained no relief from local applications and Roentgen exposures, but the pruritus was practically conquered with four sacral injections, the first two of 20 c c of 0 9 per cent saline plus 0 1 and 0 15 gm novocain, the last two of 48 c c of water with 0 4 gm novocain Once in a great while there is a little itching still, but it is mild and transient In another case the itching showed no modification after sacral injection of 48 c c of 4 5 per cent saline containing 0 24 gm novocain Eight days passed with no apparent improvement, then suddenly the pruritus ceased, and there has been no return of the itching during the ten months to date This patient was a clerk of 30 and the pruritus had tormented him for two years, involving the entire genito anal region, but he has been entirely free from it since the eighth day after the injection last February Holland reiterates that the practical result harmonizes with the theoretical reasoning, the benefit being constant and striking, while the injection can do no harm at the time or later The effect seemed better when water was the vehicle rather than saline and when from 0 2 to 0 3 gm novocain was used In some of the cases the anesthesia in the region was not complete but the pruritus was relieved At first he used but little fluid, but later injected more until he felt a resistance With a little overpressure the fluid works its way into the nerves better In three of the cases the pruritus might be regarded as of the senile type, the men being from 60 to 66, the others were in the thirties The technic was that described by P Bull and W Enderle (mentioned in THE JOURNAL, Aug 14 and Sept 25, 1915, pp 658 and 1147 It is practically the same as Cathelin's epidural injection)

124 **Corneal Cyst**—The boy of 10 had a typical corneal sclerotic cyst in the right eye Epithelium cells had invaded the anterior chamber and secondary glaucoma developed The microscopic findings in the enucleated eye are reproduced

125 **Gastro-Intestinal Polyposis**—Ingebrigtsen's report is based on sixteen cases of polypous adenoma in the stomach the patients all over 40, and one case of intestinal polyposis in a man of 36 In two of the stomach cases there was also a cancer in the stomach, and in one case there was actual gastric polyposis

126 **Traumatic Aneurysm**—Johannessen reports practical experiences in the war and much experimental research on dogs to determine the effect on the venous circulation of ligation of the corresponding artery The venous circulation dropped very low after ligation of an artery The animals were all under the influence of a general anesthetic Lying on the back the pressure in the femoral vein after ligation of the femoral artery was 7 mm mercury, in the Trendelenburg position it was from 4 to 2 mm , after compression of the femoral artery, it was 1 5 mm, and after compression of the abdominal aorta only from 0 5 to 0 mm or below This low pressure sucks the blood from the arterial collaterals directly into the veins The larger the artery, the greater the drop in the venous pressure, and this hinders the development of good collateral arterial circulation These and other experiments related teach the lesson that ligation of the vein after ligating the corresponding artery, promotes the arterial collateral circulation

127 **Herpes Zoster**—Magnus has been investigating the sensory and motor disturbances accompanying or following herpes zoster and reports here seven cases in which there were motor disturbances In the eight other acute cases and twenty-three convalescents there were no motor symptoms He and others have published a few necropsy reports showing disseminated foci of myelitis following herpes zoster, and in one case of herpes zoster he found diplococci in a round cell infiltrate in the anterior grey cornu The eight cases with motor disturbances are described in detail, with illustrations The weak muscles corresponded to the region innervated by the nerve involved in the herpes zoster The region that had been involved in the herpes zoster was often left also with sensory anomalies for a few months

SUBACUTE AND LATENT INFANTILE SCURVY

THE CARDIORESPIRATORY SYNDROME (A NEW SIGN)

ALFRED F HESS, MD
Professor of Clinical Pediatrics University and Bellevue Hospital Medical College
NEW YORK

In previous papers on this subject[1] it has been established, I believe, that infantile scurvy may be brought about by a diet of pasteurized milk An investigation of this question seemed not only indicated but also urgent in view of the increasingly widespread use of pasteurized milk, and of the fact that the National Commission on Milk Standards, a committee of the highest authority, has expressed the opinion that the heating of milk, as carried out in the course of pasteurization, does not destroy its enzymes or other chemical constituents[2] As stated, my experience did not coincide with this opinion On the contrary, I found that when the use of orange juice was discontinued in the dietary of a group of infants who were being fed on milk which had been subjected to a temperature of 140 F for thirty minutes, some of them in the course of from two to four months showed signs of mild scurvy That these manifestations were in reality scorbutic, and furthermore that they were attributable to the pasteurized milk, was proved by their rapid disappearance when orange juice was again added to the dietary, or when raw milk was substituted for the heated milk The practical deduction from these observations is not, however, that pasteurization should be discouraged, or that milk treated in this way is objectionable, but merely that the important fact should be recognized that it is not a complete food for infants and that it is imperative to give an antiscorbutic substance in addition[3] When this prophylactic measure is observed, fresh pasteurized milk becomes a most valuable food for infants, and is to be highly recommended on account of the security which it affords It should be understood that my position in regard to the effect of pasteurized milk is not based on mere refinements of diagnosis, or on rare and exceptional cases, such as are of interest only to the specialist On the contrary, I believe that scurvy brought about in this way is not at all infrequent, that it is indeed the most common cause of scurvy, and that it induces a type of the disorder which generally passes unrecognized If we are to diagnose scurvy promptly, and not overlook its more subtle manifestations, the classic textbook description of this disturbance must be supplanted by one which is less crude and more faithful to true clinical conditions

The stereotyped picture of infantile scurvy, and the one which this term commonly suggests, is that of a poorly nourished infant, lying with one or both thighs flexed on the abdomen, who, on closer examination, is found to have bleeding, spongy gums, and enlargement of the lower end of the femur, associated with exquisite tenderness This is the syndrome which the medical student carries away to guide him in his everyday practice It is the florid type, encountered only occasionally, and requiring merely a routine physical examination for recognition The commoner form, which may be termed "subacute infantile scurvy," is composed of a large number of symptoms which are inconclusive individually, and may well escape a correct interpretation The affected baby is usually in the second half of the first year of life, and does not gain or gains but slightly for weeks It may be fairly well nourished, but is pale, with perhaps slight edema of the eyelids The mother or nurse complains that the child is irritable and peevish, and that the appetite has diminished The gums may show merely a lividity or slight peridental hemorrhage, which on subsequent examination is no longer visible, and may have consisted merely of a rim of crimson edging the borders of the upper gum, or perhaps have been situated behind the upper incisor, as Still[4] pointed out On closer examination it may be observed that the papillae of the tip of the tongue are markedly congested, and that a petechial spot is to be seen on its frenum, on the palpebral conjunctiva, or here and there on the surface of the body, more especially where there are erosions, eczema or other skin lesions[5] Attention may be called to tenderness of the lower thighs, which in some instances is definite, in others so ill defined and fleeting that it is impossible to feel convinced of its significance or even reality There may be slight edema over the crests of the tibia, of the kind which does not pit on pressure The knee jerks are almost always markedly exaggerated The urine is found to be normal or to contain some albumin and red and white blood cells

[2] Report of the Commission on Milk Standards appointed by the New York Milk Committee Pub Health Rep May 10 1912

[3] In referring to pasteurized milk as inducing scurvy I do not wish to state that the heating is necessarily altogether responsible for this result There may well be other contributory factors such as the staleness of the milk

[4] Still G E Common Disorders and Diseases of Childhood London 1909 p 105

[5] The extent of the petechiae and other hemorrhages in infantile scurvy depends on the individual predisposition of the child in this regard As has been pointed out this sign is due mainly to a weakness of the vessel wall and not to an alteration in the coagulability of the blood In infants who show an instability of the capillaries as manifested by the capillary resistance test' the disorder is apt to be characterized clinically by the various typical signs of hemorrhage

These symptoms do not constitute a rigid entity, but are subject to manifold variations The syndrome may be rendered less typical and more difficult by the fact that the infant has gained steadily rather than lost in weight, as is sometimes the case, particularly if the food has been insufficient in quantity during the first few months of life There are other symptoms worthy of note, especially those which have been disclosed by the aid of the Roentgen ray As described and portrayed elsewhere, the heart may be involved in infantile scurvy, this may be evident to ordinary physical examination, as enlargement, especially to the right, and may be accompanied by dulness and diminished breathing posteriorly at the bases of the lungs This type of enlargement is often well shown in roentgenograms, as well as a marked broadening at the base of the heart, at the site of the large vessels (Figs 1 and 2) As far as I know, attention has never been called to the latter phenomenon, and it will be referred to below in another connection Roentgenograms of the bones may show the "white line" at the epiphyses first described by Fraenkel, or a thickening of the periosteum However, too great reliance should not be placed on these signs in making an early diagnosis of this disorder, as neither are invariably present

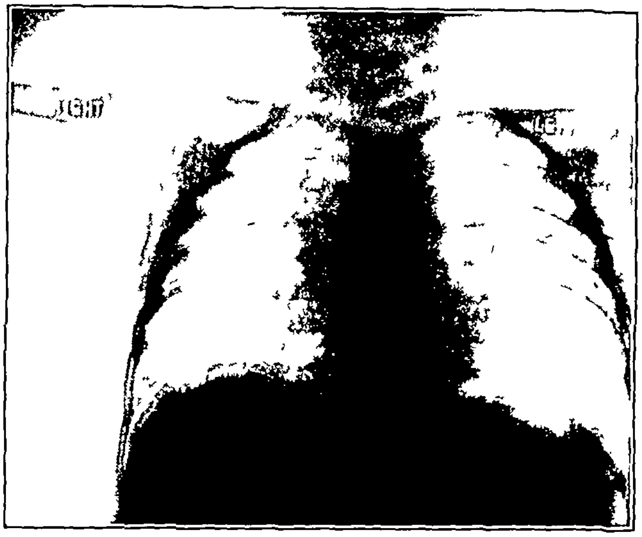

Fig 1—Enlargement of heart especially to the right and broad shadow at the site of the large vessels

An example of a case of subacute scurvy, which in many respects is typical, is the following

Case 1—I F, girl, was admitted when 3 months old, weighing somewhat over 8 pounds She was given Schloss milk, 4 ounces and then 5 ounces every three hours, and did well, weighing 11¼ pounds two months later As she failed to gain for some weeks, although 6 ounces of food were given, it was thought that this might be due to the fact that she was getting pasteurized milk and that she had never received an antiscorbutic Autolyzed yeast was tried as a prophylactic antiscorbutic, as has been described elsewhere[1] in detail This failed to cause a gain When, however, orange juice was substituted for the yeast, a prompt growth reaction resulted, a gain of 1¼ pounds in four weeks Accompanying this lack of gain in weight there were many of the other symptoms enumerated above irritability, pallor, slight tenderness of the lower ends of the femora, albumin and a few red and white cells in the urine The pulse or heart beat was frequently over 150, and the respirations 60 (Fig 3) The diagnosis of subacute scurvy was substantiated by the prompt subsidence of all symptoms when orange juice was given

Among the symptoms mentioned in this case are a pulse of over 150 and respirations of 60 a minute These phenomena were noted in several instances before their significance and intimate relationship with infantile scurvy was realized They were then made the subject of closer observation and were found to occur frequently as early signs of this disorder In one instance of subacute scurvy the pulse could not be counted, and the heart beat was found to be 200 to the minute It should not be thought that this must have been a severe case, on the contrary, the baby was in good condition, did not appear ill, and merely showed some tenderness of the thighs, and red blood cells in the urine as other evidences of its ailment When given orange juice there was a remarkable response in gain in weight and a disappearance of the other symptoms The rapidity of respirations is perhaps a more delicate indicator of this disturbance than the pulse, and has been found to be markedly affected when the latter was merely slightly increased in rate For example, in one instance the respirations were 64, 60 and 64 on three successive days, while the pulse was 124, 141 and 136 in other words, there was a 2 1 instead of the normal 4 1 pulse-respiration ratio The accompanying charts (Figs 3 and 4) illustrate the phenomenon in all its details better than a verbal description There are several points in connection with them to which I wish to call especial attention First and foremost is a reaction which is evident from a glance at either chart, the sharp drop in the pulse and in the respiration rate when orange juice was given This is the essence of the phenomenon, a response which proves that it is dependent on and the result of the scorbutic condition In Figure 4 it will be noted that after orange juice had brought about this reaction, potato was substituted and was able to enhance the effect still further It did this not only as regards the pulse-respiration syndrome, but also as regards the other scorbutic manifestations This is the case which was cited recently[1] to raise the question as to possible differences between the various antiscorbutics, and from which the inference was drawn that they are not *all exactly alike in their chemical nature or therapeutic action* My previous opinion on this question is further

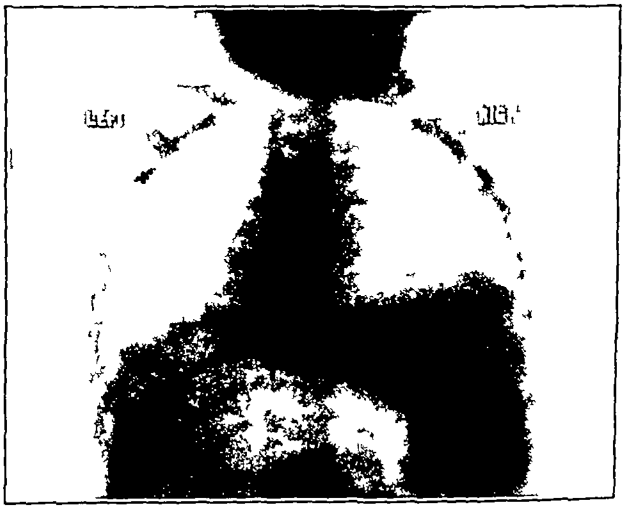

Fig 2—Broad shadow at the site of the large vessels

strengthened by the secondary beneficial results which may follow the administration of vegetables in cases of scurvy in which orange juice has been taken for some weeks (Fig 5) Returning to a study of Figures 3 and 4, we note that on giving orange juice, not only were the pulse and the respiration affected, but the temperature as well It would seem as if this disorder incited a mild febrile reaction, which yielded promptly to antiscorbutic treatment and should therefore be regarded as scorbutic in nature, in other words, as a *scorbutic fever*

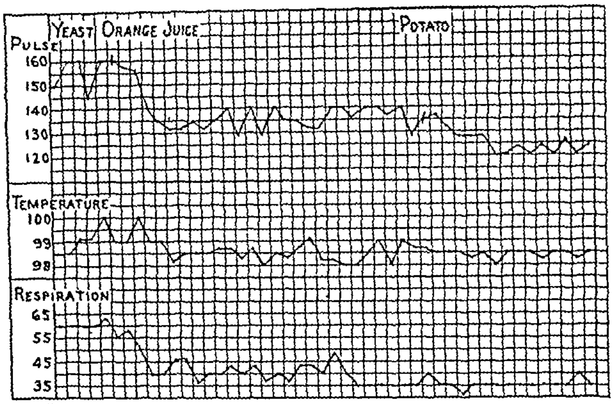

Fig 3 (Case 1)—Chart of I F aged 7 months showing prompt effect on pulse, respiration and temperature of substitution of orange juice (30 c c) for autolyzed yeast (30 c c) and a further response when the former was replaced by potato (15 gm)

There is little to be stated in addition concerning the type of the tachycardia The pulse is regular and moderately strong, and its rapidity is heightened unduly by the incidence of minor intercurrent infections Cardiographic tracings, which were kindly carried out by Dr B S Oppenheimer, showed a simple tachycardia, such as is common to exophthalmic goiter, with the T-wave exceptionally tall in some tracings (Fig 6)

The increase in respirations is a polypnea rather than a dyspnea The baby lies apparently in comfort while the respirations number 60 a minute It is probably due to this lack of visible disturbance, this superficial appearance of normal cardiac and respiratory functioning, that these signs have escaped observation In the comprehensive report of the American Pediatric Society,[6] there is no reference to involvement of heart or lungs

Without doubt this cardiorespiratory syndrome is occasioned by a disturbance of the nervous mechanism controlling this dual system In view of the fact that the action of the lungs as well as that of the heart is affected, there can be no question of the symptoms being attributable to a primary muscular alteration Nor can they be ascribed to anemia In the first paper of this series by Hess and Fish,[1] it was shown that infantile scurvy is generally accompanied by only a mild grade of secondary anemia Furthermore, observations carried out to control this point have demonstrated that poorly nourished infants with more marked anemia have approximately a normal cardiac and respiratory rate Moreover, the fact that these symptoms yield precipitously in forty-eight hours to antiscorbutic diet does away with all questions of their dependence on malnutrition or anemia The phenomenon is clearly neurotic in nature and probably due to an involvement of the pneumogastric nerves We have here, therefore, one more link of evidence that the nervous system is involved in infantile scurvy, and that this disorder should no longer be regarded as affecting only the bones and the blood vessels, or as one characterized clinically by subperiosteal swellings and hemorrhages in various parts of the body Elsewhere[1] I have laid stress on the fact that the optic nerve may show changes, and that it is quite common to find the knee reflexes exaggerated The significance of showing that infantile scurvy possesses an aspect which requires it to be regarded as a disease of the nervous system is interesting in itself, but gains far greater importance when we consider that this association brings it into closer relationship with beriberi, adult scurvy, pellagra and the ever increasing group of disorders which are classed as "deficiency diseases," or, according to Funk, "avitaminosen" In beriberi, as well as in infantile scurvy, there is enlargement of the heart, especially of the right heart,[7] and there are tachycardia, polypnea, and generally increased knee jerks In adult scurvy we find dyspnea, palpitation and hyperesthesia frequently described Attention has been drawn, from time to time, to the close clinical relationship between adult scurvy and beriberi by various observers who have noted cases of these disorders manifesting themselves under apparently identical conditions Only recently this was once more reported by a military surgeon in relation to the troops in Mesopotamia and the Dardanelles[8] In tracing relationship with pellagra, we are treading on disputed ground I would draw attention to the fact, however, that in this disease the pulse is frequently rapid,[9] and also that pathologic and even clinical changes have been found in the central nervous system[10] As is well known, skin lesions are also one of the characteristic signs of pellagra It is therefore worthy of comment that in infantile scurvy, redness of the skin is not infrequently associated with edema over the tibia, this was the case in sixty-nine of the 190 instances of edema

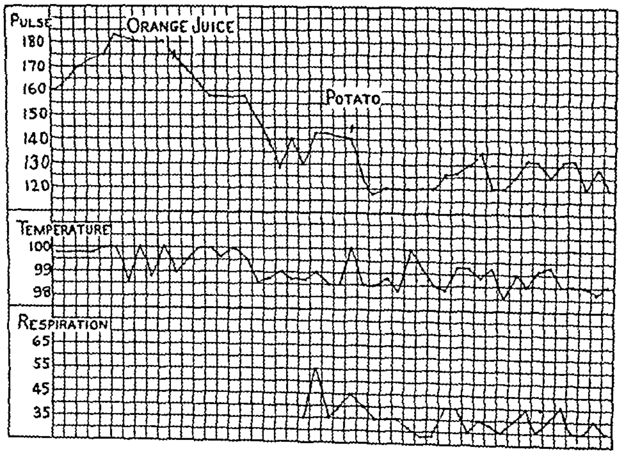

Fig 4—Chart of J G, aged 9 months, howing marked effect of orange juice (30 c c) on the *polypnea* and accessory effect of potato (15 gm) The respirations were not recorded in the early stage of this case

collected by the American Pediatric Society[6] It is also of interest in this connection, that, as has been pointed out,[1] there is an eczema which develops in infants in the course of scurvy which yields promptly to antiscorbutic treatment

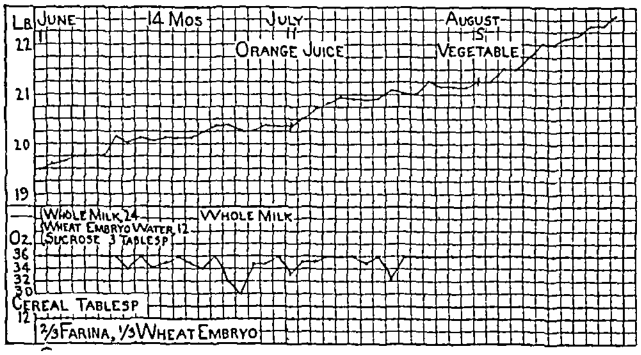

Fig 5 (Case 3) —Latent scurvy in older infant disclosed by therapeutic test child had received both wheat embryo and watery extract of the embryo

It is evident that previous to the onset of scurvy there must be a period during which the equilibrium of the essential substance or "vitamin" is no longer being maintained, but, on the contrary, a negative balance is in progress Although at the onset this abnormal state of metabolism is of no clinical moment, if it continues it gradually brings about a condition of "latent scurvy" This nutritional state may constitute merely an introductory phase to the occurrence of subacute or of florid scurvy It may, however, advance no further, the negative balance may be slight, and the supply of "vitamin" sufficiently great to maintain the body in the latent scorbutic condition for months, until, quite unintentionally, it is brought into equilibrium by the addition of some antiscorbutic food stuff to the dietary Figure 7 is reproduced to illustrate how latent scurvy may remain latent, how it may gradually merge into subacute scurvy and develop no further, and, finally, how the typical gradation may ensue, of latent, subacute and florid infantile scurvy

The diagnosis of latent scurvy is based mainly on the reaction to specific therapy, and on the marked improvement when orange juice, potato or other antiscorbutic food is taken The symptoms themselves are suggestive but do not permit a definite diagnosis In my experience the course has been as follows The infant generally has been from 6 to 9 months of age, and has been fed for a considerable period on pasteurized milk, this may or may not have been prepared with cereal decoction, nor did it seem material whether or not gruels also had been given When about 6 months of age, the baby ceased to thrive, to gain satisfactorily, to look strong and to eat as we should desire The most careful physical examination has failed to solve the difficulty On the other hand, the history of a diet of heated milk and lack of antiscorbutic food, considered in conjunction with the pallor and lack of appetite, the increased knee jerks, and perhaps the cardiorespiratory syndrome, has awakened suspicion and led us to prescribe orange juice, with a view to diagnosis as well as treatment The result frequently has been magical The following case, the weight chart of which is reproduced (Fig 8), is fairly typical of this abnormal nutritional state

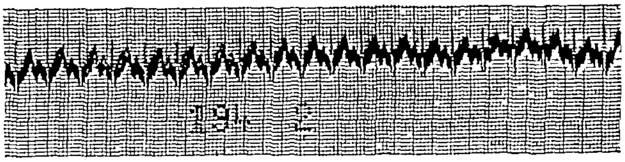

Fig 6 —Electrocardiogram in case showing cardiorespiratory syndrome

Case 2 —H C, boy, born Dec 15, 1915, was artificially fed until admitted to the institution, Jan 4, 1916, when he weighed 6½ pounds He was given 28 ounces of Schloss milk a day (This was prepared from pasteurized milk which was not heated a second time It contains per liter [quart] 140 c c of whole milk, 140 c c of 20 per cent. cream, 50 gm of dextrimaltose, 5 gm of plasmon, 0 2 gm of potassium chlorate, and 700 c c of water) By March 1 he weighed 9 pounds, and gained three quarters of a pound more in the course of this month During April he gained only 4 ounces As will be seen from the chart, there was almost a cessation of gain from April 10 to May 3, although yeast was added to the diet. May 2, orange juice was given The weight advanced at once, the general appearance quickly improved, and an eczematous condition of the face rapidly healed It will be noted from the chart that all this occurred, although the intake of food remained the same

Epicrisis a baby 4 months old with latent scurvy, which had existed since or even before it was 3 months of age

This disorder may occur in older infants, under similar dietary conditions The following case relates to a well nourished, active, contented baby over a year old A diagnosis was impossible from the signs and symptoms, but was suggested by previous experience with the results of a prolonged diet of heated milk (Fig 5)

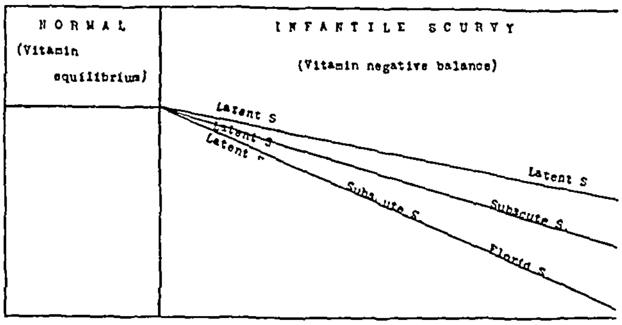

Fig 7 —Various courses which the scorbutic condition may follow according to the degree of negative balance of vitamins

Case 3 —E F, girl, admitted when 4 months old, weighing 9½ pounds, had never been nursed She gained on a mixture of two-thirds milk, and was given orange juice when 6 months of age, and vegetable a month later Feb 1, 1916, when she was 9½ months old and weighed 16½ pounds, orange juice and vegetable were discontinued, and a cereal containing wheat embryo (germ meal) substituted She had grip, associated with otitis and adenitis, during the latter part of February and again in March and the early part of April By May 14, however, she weighed 19 pounds and showed no scorbutic signs whatever About this time the watery extract of the germ meal was added to the diet in place of barley water (12 ounces a day) During June the gain fell off markedly, but the baby appeared well otherwise Whole milk was ordered to offset this in the beginning of July, but did not bring about a gain Then orange juice was added Figure 5 shows the prompt response, which unfortunately was soon interrupted by another grip attack Later vegetable was substituted for orange juice, and occassioned an increase in weight which lasted for many weeks

This condition of latent scurvy is probably the commonest type of the disorder, especiallly in the larger cities where almost the entire milk supply for infants is pasteurized, and it is frequently passed over unrecognized Most infants happily are given orange juice by the time they are 6 months of age, and may receive a small amount of vegetable or potato before they are much older, so that they are protected from serious harm in this way But there is no doubt a considerable number, including those who are peculiarly susceptible, who pass through the state of latent scurvy

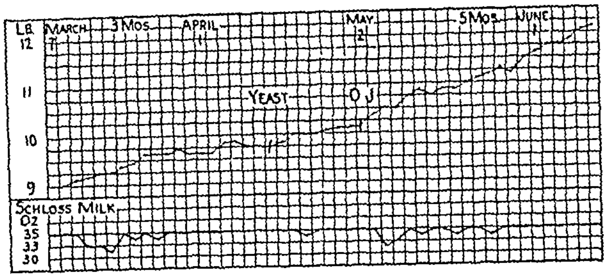

Fig 8 (Case 2)—Latent Scurvy Infant under 4 months of age responding promptly to orange juice (previous failure of autolyzed yeast), quantity and composition of food unchanged throughout

If these cases were included in the computations, we should not class infantile scurvy as a disorder which very rarely occurs during the first six months of life, nor would an experienced observer, such as Still,[4] state that "in no case did scurvy begin before the age of 5 months" An instance has just been cited occuring considerably before this age The lesson taught by these observations is not that fresh milk for infant feeding should not be pasteurized, but that the administration of antiscorbutics should be begun earlier There is no reason based on clinical experience which contraindicates the giving of a teaspoonful of orange juice at 1 month to bottle fed babies, and of gradually increasing this amount to a tablespoonful at the age of 3 months As has been repeatedly shown, there is, on the contrary, a valid reason for urging the adoption of a prophylactic measure of this kind for infants fed on the pasteurized milk as supplied at present

CONCLUSIONS

An exclusive diet of pasteurized milk will frequently induce scurvy in infants It should be well understood, however, that this danger can readily be averted by the mere addition of an antiscorbutic food to the dietary

Probably a large proportion of infantile scurvy is occasioned at present by our pasteurized milk This scurvy is usually not of the classic, florid type It is less pronounced and obvious, and is consequently the form which is least often recognized This type may be termed "subacute infantile scurvy" and is distinguished by a group of incompletely developed symptoms which disappear quickly when orange juice or other specific therapy is given

Another type found to be occasioned by this milk is "latent scurvy" This constitutes a state of malnutrition which develops slowly as the result of a negative balance of "vitamins," It can rarely be definitely diagnosed, except by the sharp recession of symptoms —stationary weight, pallor, poor appetite, etc—following the administration of an antiscorbutic

We should no longer regard infantile scurvy, from either a pathologic or a clinical point of view, as a disorder affecting merely the blood vessels and the bones Roentgenograms show that the heart, especially the right heart, is frequently enlarged, and that there is a broadening of the shadow at the base of the heart, at the site of the great vessels Furthermore, this disorder is associated frequently, even in the mild forms, with a cardiorespiratory disturbance characterized by a very rapid pulse, and respirations which may rise as high as 60 a minute (polypnea) Both of these signs disappear promptly when orange juice or potato is given This cardiorespiratory syndrome is due to an involvement of the nerves Considered in conjunction with the changes of the optic disk, previously described, and the increasing of the knee reflexes, it is evident that the nervous system is extensively involved in infantile scurvy This fact gains added interest in view of the marked involvement of the nervous tissue in other so-called "deficiency diseases," such as adult scurvy, beriberi and pellagra

ASTRAGALECTOMY (WHITMAN OPERATION) IN INFANTILE PARALYSIS*

W R MacAUSLAND, M D
Surgeon in Chief, Orthopedic Department Carney Hospital
BOSTON

It is not my object to discuss more than in a general way the various operative procedures in the paralyzed foot, but rather to emphasize the value of an operation which has stood the test of time, and unlike tendon transplantation, silk ligaments, etc, has been found practical, efficient and permanent in combating the instability so frequently seen in the paralyzed foot It seems to the writer that except for one or two possible conditions in the paralyzed foot, transplantation should be discarded in favor of a procedure giving permanent results in the hands of the surgeon As one compares the results in a series of cases some years after operation, it seems quite remarkable that transplantation of tendons and the use of silk ligaments still persist

Infantile paralysis most frequently leaves its mark in the muscles of the foot where varying degrees of paralysis persist from a mild weakness of one group or a paralysis of one group to a total paralysis of the entire muscle strength below the knee The extent of the disability, however, only rarely coincides with the extent of the paralysis

Weakness, instability of the foot and deformities follow paralysis of one group as frequently as they follow paralysis of all the muscles It is the failure to recognize this fact that tempts the surgeon to use such insufficient means as transplantation and silk ligaments in order to combat deformity in those cases with slight loss of muscle power The normal foot is balanced by muscles working in perfect coordination, assisted by

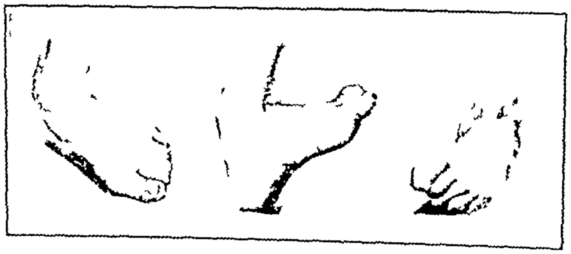

Fig 1—Three of the more common deformities in the partly paralyzed foot

ligaments which check extremes of motion To expect sufficient restoration of balance following transplantation is illogical from a mechanical and physiologic point of view, and in the experience of the writer not based on careful and prolonged clinical observation

---

* Read before the Section on Orthopedic Surgery at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

Our first duty, of course, is to foresee and prevent structural deformity, thereby favoring regeneration and recovery of power

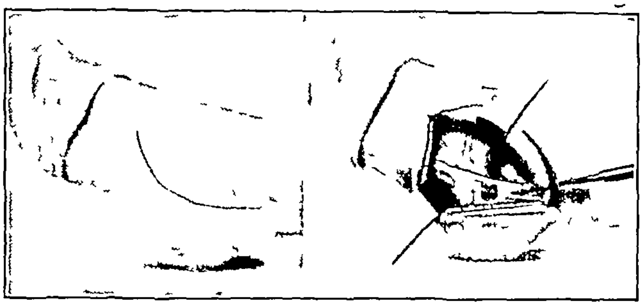

Fig 2 —Astragalectomy — the Whitman operation On left line of incision On right, tendon of peroneus longus exposed tendon of peroneus brevis being exposed

If this recovery does not take place, then we arrive at the point where operative interference must be considered or the patient condemned to a brace for permanent support Here the question arises as to the class of cases in which surgical interference is indicated We must all believe that operative interference should be delayed as long as there is a possibility of a return of power, e g, about one and a half to two years following the initial attack In children, in whom deformity may usually be prevented, my experience leads me to wait longer if the age of 6 or 7 has not been reached In the presence of deformity not easily correctable by manipulation, this age limit may be lowered a year to hasten good locomotion

What operation shall we choose? During the past six years I have used astragalectomy as devised by Dr Royal Whitman[1] in almost all of the deficiencies following infantile paralysis affecting the leg Altogether my series comprises 135 cases, a sufficient number to warrant the formation of definite opinions concerning its value as an operation In short, I may state that it has come to replace the commoner operations of transplantation, silk ligaments and allied operations Astragalectomy gives stability, which is not in my experience obtained by the other procedures, and in addition preserves sufficient motion for good function of the ankle Arthrodesis when successful stiffens the joint and an awkward gait results

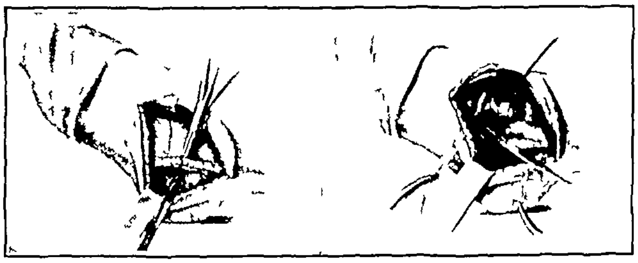

Fig 3 —Astragalectomy — the Whitman operation On left peroneal tendons sutured and divided On right, external lateral ligament divided tibio astragaloid ligament divided, interosseus and external talocalcaneal ligaments being divided

Age —Astragalectomy can be done at any age following a period of two years after the original paralysis, but if possible should be reserved until the child is 6 or 8 years old If, however, deformity is not being prevented by apparatus and if the limp is more than the extent of the paralysis warrants, then I should not wait for this age, for atrophy and shortening go hand in hand with the severity of the deformity and the limp, not with the extent of the paralysis In the period between 6 and 16 years of age the most satisfactory results are obtainable We have done the operation later but find that more sensitiveness and pain are liable to follow, and the results, in spite of good stability, motion and a good posture, are not quite as satisfactory as when done early

Indications —The conditions in the foot for which this operation may be done with benefit are many Probably the most striking results follow its use in the deformity of calcaneovalgus, for which it was originally planned (Fig 1) Here with the shifting of the tibial weight forward, and the transplantation of the peronei into the Achilles, a most striking functional result is obtained But its use cannot be limited to this alone It gives excellent and standard results in all foot conditions — even where only one muscle is paralyzed

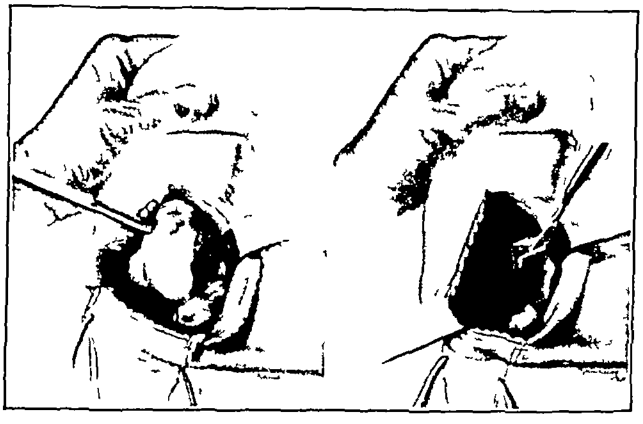

Fig 4 —Astragalectomy — the Whitman operation On left, dislocation of astragalus by strong inversion of foot Note heavy dissector under neck by which astragalus is pried loose head first On right, widening tibia fibular articulation by removal of thin slice of cartilage from internal malleolus

Operative Technic (Figs 2-10) —Here as in other joint operations the asepsis should be guarded carefully and manipulation should be gentle A curved or L-shaped incision is made around the external malleolus, tending forward over the head of the astragalus The upper flap is then dissected upward, exposing the tendons of the peroneus longus and brevis, which are then dissected free and severed just at the fibular tip The ends are caught in No 2 catgut sutures and retracted

An incision is then made through the external ligaments around the astragalus, using especial care about the head of the astragalus The foot is strongly inverted Then by placing a blunt dissector under the neck of the astragalus, the bone is pried out of position head first, and removed At once the ease of displacing the foot backward will be noticed, but in order to insure a good joint a certain amount of modeling must be done

The internal lateral ligament is dissected upward from the internal malleolus, if necessary, a strip of cartilage is removed from both tips to span the scaphoid and cuboid, a small piece is excised from the side of the scaphoid and cuboid to form pockets for the malleoli The foot is then displaced backward and held carefully in this position to insure the proper relations in the new joint A moderate equinovalgus gives stability while holding The peronei are disposed of by suture to the Achilles tendon, by tendon fixation or by resuture to the distal ends of the tendons of the peronei, as indicated in the given case The skin is closed with catgut and plaster applied from the toes to midthigh with the knee flexed and the foot in equinovalgus The leg is kept elevated for a period of ten days, after which crutches may be used The first change of cast takes place in three or four weeks, at which time the equinus is corrected to a right angle in cases of quadriceps paralysis or left in 5 to 8 degrees equinus where the quadriceps is present Valgus should persist throughout the treatment

---

[1] Whitman Am Jour Med Sc 1901 **122**, 593 Am Jour Orthop Surg, 1910 1911 **13**, 137 Am Surg 1911 **54**, 860

A leather shoe (Fig 11) is then put over the plaster and the child allowed to walk, changing the plaster as necessary for five to six months Following its removal a shoe with a lift on the outer side of the sole is used A one-half or three-quarter inch cork lift under the heel will compensate for the shortening of the leg and improve the gait Circulation improves rapidly with the return of good function and loss of growth ceases, the paralyzed leg beginning to grow at a rate equal to that of the well side

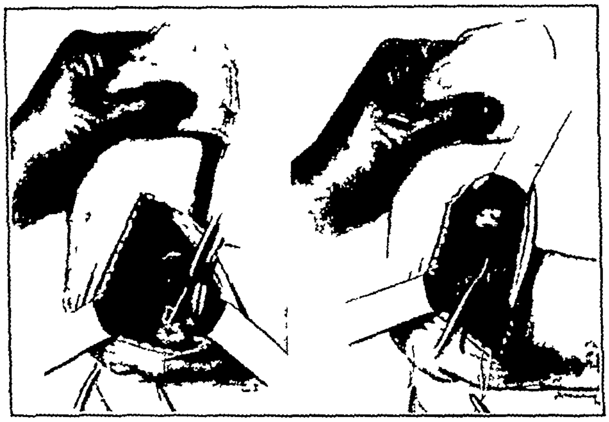

Fig 5 —Astragalectomy — the Whitman operation On left, widening the tibia fibula articulation by removal of thin slice of cartilage from one or both the internal lateral ligament has been dissected up to sharpen the malleolus On right the new articulation for internal malleolus Note removal of inner one fourth to one sixth from inner side of scaphoid thus forming pocket for sharpened internal malleolus

Conclusion—The results obtained with astragalectomy have led me to discard, except in the rare cases, all other procedures

LITERATURE

Various methods for remedying the condition have been devised Amputation of the foot in cases of severe deformity is advocated by Watson[2] I know of no other report on this operation Lange's silk ligaments are advocated by many authors, among whom are Allison,[3] Bradford,[4] Barton and Plummer,[5] and Lovett[6] Rich[7] says that they are of use in joints where there is no external irritation, as there is in the ankles from shoes Here he advocates capsule tucking Nerve grafting is advocated by Spitzi and others The general opinion has been summed up by Feiss,[8] who says there is no experimental evidence to justify its use in paralytic cases Tendon transplantation has its chief advocate in Vulpius[9] Soule[10] advocates arthrodesis of the astragaloscaphoid joint, with the use of a bone peg to aid ankylosis

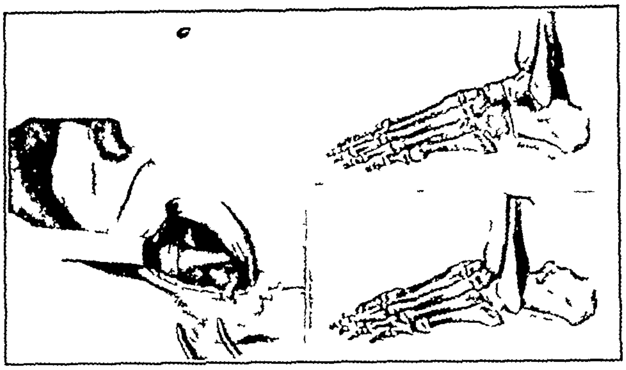

Fig 6 —Astragalectomy — the Whitman operation On left, the external malleolus rests in a similar socket over calcaneocuboid joint Note backward displacement of foot, and fibula carried well forward On right above normal relation of tarsal bones below, relations following the properly done astragalectomy

The operation of astragalectomy was first performed in 1842 by Lund[11] of London for the correction of a very severe talipes, and its use has since been reported by numerous authors, usually in traumatic and infectious cases Willens[12] reports in 1911 its use in cases of clubfoot in an operation devised by him Peraire[13] used it with goods results in a case of traumatic paralytic equinovarus In none of these was the foot displaced backward Its use in paralytic talipes was first advocated by Dr Whitman in 1901 The operation briefly consists of the enucleation of the astragalus, fibro-arthrodesis of the joint, transplantation of the tendons, and the backward dislocation of the foot The cases in which it is serviceable have since been much extended by Whitman Favorable results from the operation have been reported by Dane and Townsend[14] in a series of cases from the Childrens' Hospital, Boston, and also by Lord[15] and others

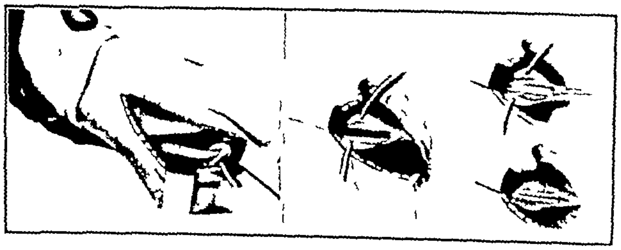

Fig 7 —Astragalectomy — the Whitman operation Disposition of tendons of peronei into the Achilles tendon and resuture and tendon fixation (Galli operation)

The operation has been modified by Robert Jones,[16] who divides it into a two part procedure His method is not much used in this country Tubby[17] modifies the operation by using Lange's silk ligaments to strengthen the Achilles tendon after division

Tendon fixation separately or as an adjunct to astragalectomy has been used by the author in several of his later cases with good results

ABSTRACT OF DISCUSSION

Dr Frederick C Kidner, Detroit I can agree with Dr MacAusland in the use of the Whitman operation, in selected cases, but I cannot feel that so mutilating an operation is necessary in a large portion of paralyzed cases He has spoken of the rapid growth of the foot following the operation because of the restoration of function We know that growth can be stimulated to a great degree by ordinary massage, heat applications and other therapeutic measures Therefore, this argument for the operation is not very strong As to the function, there is no doubt that the strong, firm foot resulting from astragalectomy is a very useful one, but so are many feet which wear light braces or are in moderate valgus or varus To my mind, astragalectomy should be limited to severe cases of paralysis in well grown feet

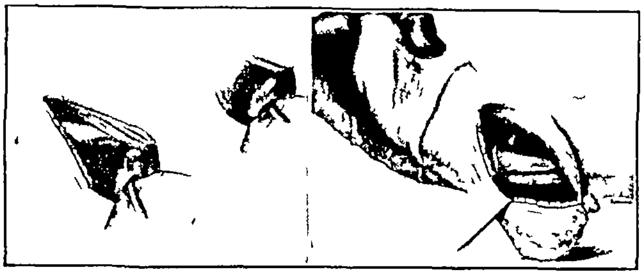

Fig 8 —Astragalectomy — the Whitman operation Disposition of tendons of peronei, into Achilles tendon, and resuture of ends

Dr J D Griffith, Kansas City, Mo It seems to me that we have discarded transplantation of tendons, and that if we are discarding the silk ligaments, we have to come to the Whitman operation Dr Whitman has shown before, and Dr MacAusland is now showing, that this surgical interference is not interfering with growth in length, size or the function of the foot to any great extent In these cases of equinovalgus and equinovarus, particularly valgus with calcaneus, there is nothing left to do but this operation

Dr Albert H Freiberg, Cincinnati A few years ago, Dr Whitman felt that the profession was somewhat tardy in recognizing the value of his operation, and I think that events have fully justified him in his attitude I feel, however, that if he were here today, he would have just as much objection to the trend of events, now that the pendulum has swung too far the other way There is no question in my mind that his operation has great advantage in suitable cases I have used it, and shall use it, I hope, very often On the other hand, it seems to me that there is something wrong with the tendon transplantations of the man who says that tendon transplantations must be given up, to have their place taken by a mutilating operation such as this is, even under most favorable conditions We have learned that we had expected too much of tendon transplantation We have also learned that the complicated procedures had to be abandoned, and that it was not possible to convert a flexor into an extensor, or an extensor into a flexor, ad libitum, because the muscles would fail to respond to unreasonable demands made on them There are certain psychologic problems to which the brain will not respond It seems to me, however, that many of us—evidently not all of us—must have cases of tendon transplantation, done under more or less ideal conditions, which have stood the test long enough to make it impossible to deny the considerable advantages that the patients have received from the operation It is further understood by men of experience that we cannot switch muscles around as we please and sew them down in an insecure way and have the tendons move freely in the proper direction We have learned that in cases in which there is fairly isolated paralysis of the tendons about the foot, we may be able to pass tendon under the annular ligament, the tibialis anticus, for instance, and in that way get an excellent result which will stand the test of time, and produce a foot of a degree of functional perfection that is not at all to be compared with the most delightful result after the Whitman operation, useful as that procedure may be in extensive paralysis

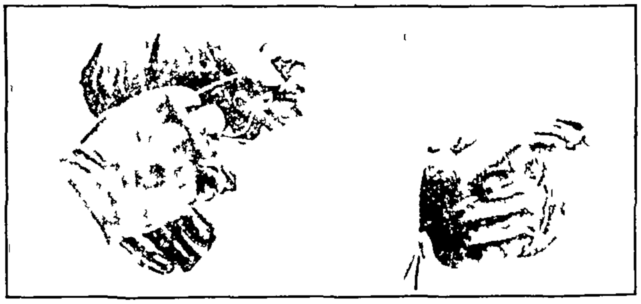

Fig 9 —Astragalectomy — the Whitman operation Note the posterior displacement and the position in which the foot is being held during suture and the application of plaster with the knee flexed and the foot in slight equinovalgus

Dr C M Jacobs, Chicago I want to ask Dr MacAusland what is his average shortening of the limb in his series of cases following this operation I would also like to ask him whether he has done any other operation—say the Galli—for a calcaneus condition I was always in favor of the Whitman operation until I tried Galli's method of inserting the Achilles tendon into a groove on the posterior portion of the tibia My first case, which was done a year ago, gave such excellent result that it led me to discard the Whitman operation for paralytic calcaneus

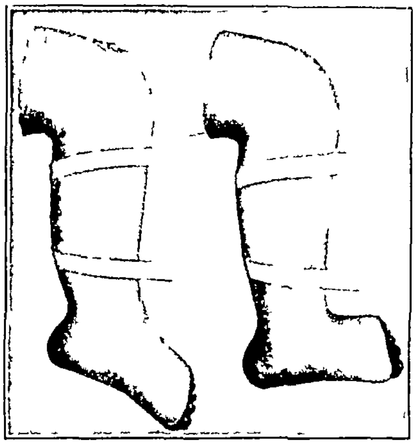

Fig 10 —Astragalectomy — the Whitman operation In plaster following operation

Dr Edwin W Ryerson, Chicago The Whitman operation is a very valuable one, but it is not applicable to every type of paralyzed foot Dr MacAusland goes just a bit too far in this The Whitman operation should not be performed in cases in which there remains strength in the calf muscles The tibia should not be displaced forward on the foot, because a very undesirable degree of equinus is likely to result I have seen this in some cases In cases in which these muscles are strong, one should do astragalectomy, if it is indicated, and should not displace the foot backward on the tibia I consider that tendon transplantation is by no means obsolete, no matter what you may have gathered from the statements that have been made It remains today an extremely valuable, and the only proper, operation for certain forms of paralysis The fact that a foot has simply weakness or infantile paralysis is no more reason for doing a Whitman operation than for extracting the patient's teeth The cases must be considered carefully and individually The Whitman operation is not applicable to certain cases, and should not be done in them The cases in which it is especially desirable are cases in which there is great lateral mobility of the foot, where the foot rests on a very freely movable astragalus and is not stable In cases of dangle foot, the Whitman operation, as performed by Dr MacAusland, is very valuable, and is the best procedure devised, but in cases in which tendon transplantation can be done—and there are many such cases—do not remove an astragalus unless it is necessary I have dozens and dozens of cases in which the results of tendon transplantation are satisfactory to both the patients and myself, and I have other cases in which they are not satisfactory, because we hoped for too much from the operation in the past We cannot cure a foot that is very badly paralyzed by tendon transplantation, but it has a wide field of application in cases of moderate or isolated paralysis Such cases can be treated beautifully in this way, and we should not discard the operation of tendon transplantation, which is a therapeutic resource of the greatest possible value in properly selected cases

---

[17] Tubby Clin Jour 1912 1913 **40**, 163

DR. W C CAMPBELL, Memphis, Tenn I have operated in this way in thirty cases with excellent results, but my cases have been selected cases The type of case in which I found the procedure most satisfactory was calcaneovalgus in which there was considerable power remaining in the peroneal muscles Out of these thirty cases, or over I have had two that have had some inversion afterward The inversion has not been severe and has been correctible by tilting the shoe I now always tilt the shoe in such cases I have also employed the method of tendon fixation to the external malleolus and fibula to prevent inversion It is very important to maintain the right position in putting the foot in plaster It should be placed in an overcorrected valgus position as well as in moderate equinus with backward dislocations

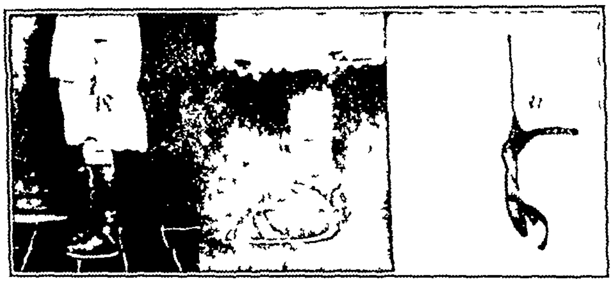

Fig 11 —Shoes to be worn after Whitman astragalectomy

DR J T RUGH, Philadelphia Some of those present saw an operation in Philadelphia about two years ago that combined exactly the same principles as the Whitman operation It has not received the attention it deserves It is the Davis operation and he has chosen to call it "the transverse horizontal section" I have always felt that the Whitman operation was essentially indicated in cases of the calcaneus type of paralysis, and the Davis operation combines the same principles as the Whitman but does not remove the astragalus The disadvantages of the Whitman operation is the increase of shortening, which must be compensated for by tilting of the foot, with slight resulting equinus In the Davis operation a transverse osteotomy is done below the astragalus, that is, between the astragalus and the calcaneus The posterior calcaneo-astragaloid articulation is separated, and the foot is displaced backward and put in the position of slight equinus A tendon transplantation can also be done, or where there is no power in the peroneus and where there is a total loss of the Achilles tendon, I have been doing the Putti operation, cutting off the tendon from the muscle and transplanting the tendon into the tibia a little differently from the way in which it is done in the so-called Galli operation, with excellent results—making an absolute ligament of the tendon

DR R L HULL, Oklahoma City I have done the Whitman operation in from fifty to seventy-five cases This operation was originally devised for cases of calcaneus and calcaneovalgus and it is better for them than any other operation I have done it in a patient 3 years old, and I have done it in adults of 21 and 24 years In every case in which the patient is from 3 to 6 years old, I approach the operation with a great deal of enthusiasm, because I know that I can give the patient the best possible functional result—better than from any other operation or series of operations Recently I have been a little more radical, and have been doing it in a few cases of varus and equinus It is impossible to know yet what the end-results will be, but at present it has seemed to meet the indications better than any other operation with which I am familiar

DR C B FRANCISCO, Kansas City, Mo In 1907 I assisted Dr Whitman in adding fifteen or sixteen cases to his original report Naturally, I have been very much interested in his operation ever since I think that if we had an operation that met the requirements in every case of deformity of the foot as well as the Whitman meets those of the calcaneovalgus deformity, we should be glad to adopt it I know what the result will be when I do this operation You can tell absolutely what you will get—what motion You will get from one third to two thirds of the normal range of motion in children under 10 years You also know pretty definitely what the foot will look like In the badly paralyzed cases, you know that there will be a little cavus, and it will take a while for the foot to flatten out, but you have no hesitancy about recommending it When you get into the varus type that, to me is the hardest deformity that I know of to cure and have stay cured One of the most distressing things is to manipulate and resect and do everything you know how to and get good position and then turn the patient out and lose track of the case, only to have the child return, a year or so later, with the deformity as bad as ever, so that you feel that you have done harm instead of good I have not, so far, used the Whitman operation in the varus type, as I am now trying out the Galli method of fixation of the peronei I believe that there are certain cases of varus in which the Whitman operation will prove satisfactory, as indicated by Dr Ryerson, the lateral movement type The operation does away with that I think that Dr MacAusland is to be congratulated on having brought the subject before us

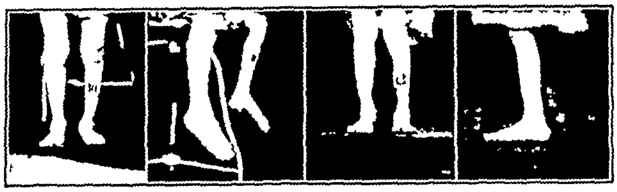

Fig 12 —Infantile paralysis valgus deformity From left to right anterior view before operation lateral view before operation anterior view twenty months after astragalectomy and lateral view twenty two months after astragalectomy

DR W RUSSELL MACAUSLAND Boston The proof of the pudding is in the eating I have not heard any one advocating the value of tendon transplantation without saying, 'In almost every case," or a similar qualifying remark I can say what my results have been in astragalectomy In one hundred and thirty-five cases, there have been only three cases of varus This is a very difficult deformity to overcome when it does occur, and it should be guarded against carefully These cases of varus all occurred in patients living out of town, some of the postoperative treatment being left to assistants The important thing is to put the foot up in valgus and slight equinus I keep the valgus during the entire treatment,

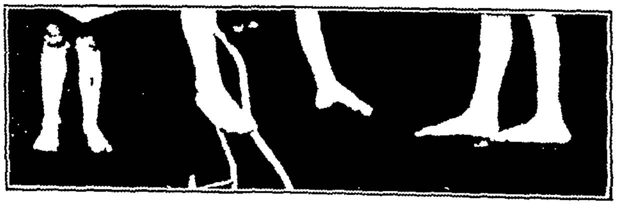

Fig 13 —Infantile paralysis calcaneovalgus deformity Anterior view before operation lateral view before operation and lateral view twenty months after astragalectomy (Whitman)

correct the equinus when the quadriceps is gone, and retain plantar flexion of five to eight degrees when the quadriceps is present Dr Freiberg's remarks carry considerable weight His results from tendon transplantations and those of many others which have come under my observation in Boston are not satisfactory I have also looked up the results of arthrodesis in young children, and found that in 90 per cent of the cases the old deformities recur or new ones appear If tendon transplantation does not add to the stability of the foot and increase its function, it is not the best operation When we take a tendon from one place and put it in another, we weaken the tendon and also weaken the side that it came from, and put it where it never can act to its full strength I did not say that I used the Whitman operation in every case If by tendon transplantation any of the surgeons here can obtain correction of the deformity, universally, increase function and secure stability, then it is certainly an operation for them on a par with astragalectomy Dr Jacobs asked about the average shortening that I obtain Astragalectomy does not shorten the leg The shortening in my cases was about ½ inch to 1½ inch In cases with the os calcis vertical the malleoli naturally lie nearer the ground following astragalectomy The Galli operation has undoubtedly a prominent place in the treatment of infantile paralysis Up to the present, however, my experience has not been such that I care to make any statements about it I shall not do so until I have formed definite conclusions Dr Ryerson says that the pendulum has started to swing too strongly in the direction of astragalectomy Dr Whitman has tried to impress the value of astragalectomy as compared with tendon transplantation before, and failed With regard to this operation it is on a similar plane with all the other surgical procedures that he has advanced Nothing has been found as a substitute for them Dr Campbell spoke of inversion I had that happen in three cases These inversions are very objectionable deformities I was able to correct them by placing the fibula further forward, holding it there by means of the Galli operation, suturing the peroneal tendons into the fibula These patients are all right now

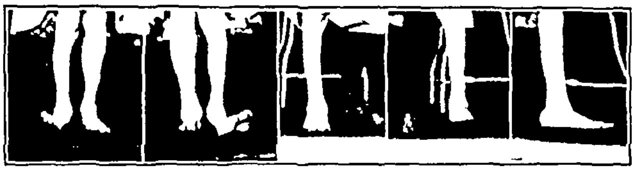

Fig 14 —Infantile paralysis calcaneovalgus deformity operation May, 1912 Anterior view before operation posterior view before operation, anterior view six months after astragalectomy (Whitman), posterior view six months after operation, and lateral view six months after operation

INTESTINAL OBSTRUCTION DUE TO ASCARIS LUMBRICOIDES

REPORT OF A CASE

J MAXIME PERRET, M D,
AND
H THEODORE SIMON, M D
NEW ORLEANS

In the latter half of the nineteenth century, opinion was divided as to the possibility of *Ascaris lumbricoides* being the etiologic factor in intestinal obstruction, thus, Leichenstern and Treves opposed this view, while Trousseau, Bretonneau and Stutz[1] upheld it, each having been among the first to report cases

Bordoroni and Stepp in 1887 reported two cases, both of which were confirmed postmortem

Simon,[2] in 1892, while holding a necropsy in a case of intestinal obstruction, found the cause to be a mass of roundworms

Botoff,[3] in 1897, reported a case of obstruction, perforation and peritonitis, in which the postmortem revealed the presence of 500 roundworms

In 1899, Taylor[4] found sixty-six worms in a case of intestinal obstruction

Zotoff[5] reports a case of Mosler and Peiper of a 3 year old girl who died of peritonitis with two perforations in the ileum, 17½ inches from the cecum, through one of these openings twenty-five roundworms projected, the ileum between this point and the cecum, ascending colon and transverse colon were completely filled with roundworms, numbering 500 in all

Van Meter[6] reports a case of a child aged 5 years, having a sausage-like mass above and to the left of McBurney's point, in which operation revealed in the lower part of the ileum a coil of roundworms causing complete obstruction, the author says that there were almost enough parasites "to fill a wash basin", the patient recovered

A case, reported by Venning,[7] of a 2½ year old boy who was operated on and died, was diagnosed before surgical intervention by palpation of the intestinal masses through the abdominal wall, 273 worms were removed, the site of obstruction being the jejunum, *ileum and cecum*

Vickery[8] was called to see a pregnant woman with symptoms of intestinal obstruction and a history of vomiting several roundworms, on being given a dose of sanotin, followed by castor oil, she vomited twelve roundworms The symptoms of obstruction disappeared, and excepting for the sudden termination of gestation, she made an uneventful recovery

Takaki[9] reports a case of acute obstruction in a 3 year old child with complete recovery following the vomiting of 115 roundworms

Having consulted the records of Charity Hospital in the ten years from 1906 to 1916, we find 112 cases of intestinal obstruction, in ninety adults and twenty-two children, and of these, there is but one case in which the roundworm is the etiologic factor The patient was a young negro girl who was operated on for obstruction A portion of the intestine was filled with a mass of worms The condition necessitated a resection of the intestine, and a Murphy button was used, shortly afterward, after some apparent improvement, the child died, and necropsy revealed the presence of a roundworm in the lumen of the button, which it occluded

REPORT OF CASE

History—M M, white girl, aged 8, was admitted to a surgical ward on the evening of March 14, 1916, having been referred by an attending physician for surgical *intervention* of what he rightly diagnosed acute intestinal obstruction The family history was of interest, as the patient's five sisters and brothers had passed roundworms on many occasions The past history was negative except that the child had frequently passed roundworms since the age of 2

Five days prior to admission, the child was suddenly taken ill with a pain in the right lower abdominal quadrant, and slight elevation of temperature On the second day she began to vomit, and this continued up to the time of admission The vomitus consisted of a clear watery fluid A dose of castor oil was given the second day and only a very small stool passed, with no more bowel movements until she came under our observation

TEMPERATURE, PULSE AND RESPIRATION

Time	Temperature	Pulse	Respiration
On admission	101	120	25
Four hours later	103	112	30
Eight hours later	102 4	116	26
Twelve hours later	99 6	100	24

Physical Examination—The child was poorly developed and nourished The skin was of a slight sallow tint The glands in neck and groin were enlarged The eyes were sunken, with dark hollows under the orbits The teeth were badly kept The tongue was dry and coated The throat, nose, ears and heart were negative Coarse mucous rales were heard over the lower half of the right lung, both anteriorly and posteriorly The abdomen was distended and tympanitic, there was no rigidity In the left lower abdomen, in the region of the sigmoid, a mass the size of a large lemon was palpated The viscera were not palpable The extremities and reflexes were negative

Laboratory Reports There was a total white blood count of 16,800 per cubic millimeter The differential white count revealed lymphocytes, 21 per cent, endothelial leukocytes, 3 per cent, neutrophils, 67 5 per cent, eosinophils, 8 5 per cent Examination of the urine revealed albumin and sugar, negative, indican, strongly positive, microscopically, a few leukocytes

After the examination a purgative enema was given, and returned colored with fecal matter and containing a mass of approximately forty roundworms, coiled and interwoven together, the size of a child's closed fist A second enema was given and returned highly colored with fecal matter The distention was relieved, and excepting for a rise in temperature the first eight hours, the patient's condition improved, and in twelve hours the temperature was but 99 6 F The patient continued to improve and excepting for an acute bronchitis, which she developed on about the seventh day, made an uneventful recovery, and was discharged as cured, April 2, 1916

Mass of approximately forty Ascarides lumbricoides × 1½ expelled in a case of acute intestinal obstruction

SUMMARY AND CONCLUSIONS

We find that although the disease is rare, there are quite a few cases of intestinal obstruction due to roundworm

Most cases are diagnosed at necropsy or on the operating table, and only seldom is the mass of worms expelled through the natural channels

Although the most drastic purgatives may be of no avail, the enema may in a few cases cause the surgeon to lay aside his knife

MECHANICAL PROBLEMS OF BRONCHOSCOPIC AND ESOPHAGOSCOPIC FOREIGN BODY EXTRACTION *

CHEVALIER JACKSON, M D

PITTSBURGH

In dealing endoscopically with foreign bodies lodged in the larynx, trachea, bronchi or esophagus, it is fundamentally necessary to remember that the problem is not simply to remove the foreign body but to remove it with little or no risk to the patient It is always necessary to remember that a patient is far safer with a foreign body in his air or food passages than he would be if the intruder were ruthlessly torn out at all hazards Ruthless withdrawal is comparable to the act of the ignorant farmer who hitches a team of horses to the malpresented calf Only in the rarest instances is immediate removal necessary, and it is far better to desist at once if at the first bronchoscopy it is found that special instruments will need to be devised to remove the intruder On the other hand, it is never wise to make the first bronchoscopy without having prepared beforehand everything that can possibly be needed so far as it is possible to foresee from a study of the roentgenogram, history, symptoms and physical signs

The experience resulting from the encounter with foreign bodies of almost all conceivable shapes and substances has resulted in an armamentarium which probably can deal with all kinds of foreign bodies When the bronchoscopist first catches sight of a foreign body for which he has been searching, the temptation to seize it by whatever part is visible and to pull on it with all the strength of which his forceps are capable is very great, and one might say that the temptation is greater directly as the duration of the search

Yielding to this temptation has been the cause of more mortality in foreign-body bronchoscopy and esophagoscopy than any other single factor Moreover, hasty, injudicious traction of this kind will very often not only fail to remove the foreign body but will so complicate the situation as to render subsequent removal exceedingly difficult In other words, the mechanical problem is converted from a very simple into a very complicated one, just as pulling on a tangled mass of string will render subsequent disentanglement difficult or impossible Therefore, it may be stated that there are three reasons why the study of the mechanical problems of foreign-body extraction constitute the most important study in foreign-body endoscopy

---

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

These three reasons are 1 Attempted endoscopic removal of a foreign body by seizure, followed by traction without proper study of the mechanical problem, ends in a high percentage of mortality

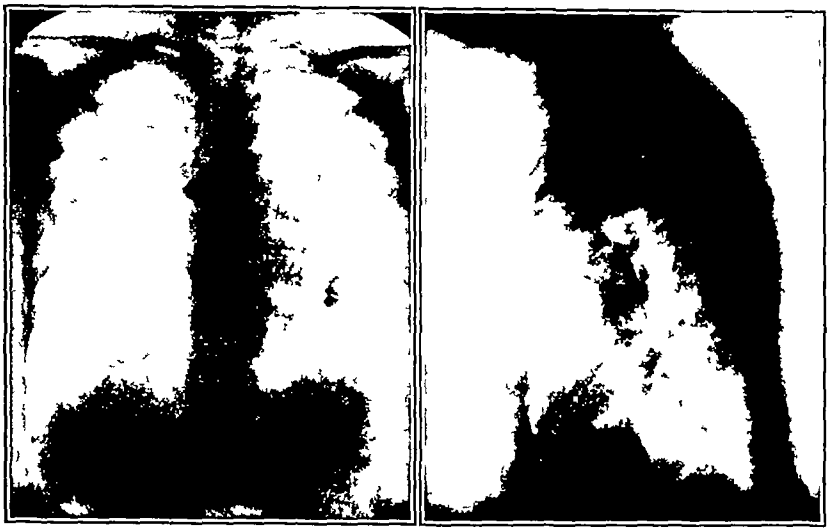

Fig 1—Roentgenogram showing an iron casting in the right bronchus of a child of 8 years The movements of the casting are shown in Figure 3 Foreign body removed by peroral bronchoscopy without anesthesia

2 Such attempts frequently fail to remove the foreign body

3 Such attempts frequently complicate the problem so as to render subsequent removal exceedingly difficult, converting an easy problem into a difficult one, or even into one impossible of endoscopic solution

Fig 2—Iron casting (actual size) from a blind roller shown in Figure 1 The hard smooth conoidal end, presenting in a tightly fitting ring of swollen mucosa, rendered difficult the finally accomplished seizure of the stem below the conoidal end

The following considerations of solutions of mechanical problems are based on the successful endoscopic removal of foreign bodies from the esophagus, larynx, trachea and bronchi, in 543 out of 550 cases (98 7 per cent) In the 550 cases, seven patients (1 3 per cent) died within a week In six of these the patient was in bad condition when admitted In only one of the seven could the death be attributed directly to the bronchoscopy The parents refused to allow a postmortem, so the cause of death could not be determined In a large proportion of the 543 successful cases, removal had previously been unsuccessfully attempted by others That success attended the efforts of Dr Patterson and myself was due not to greater skill, nor to superior instruments, but rather to the careful study of the mechanical problems involved and to the avoidance of the dangers hereinafter pointed out Some of the previously described solutions of mechanical problems are merely mentioned in connection with later statistics which confirmed the value of the methods There is much overlapping of the groups of statistics because of many cases presenting a combination of two or more problems, each of which was separately solved according to its class

The Advantages of Small Tubes—In the solution of mechanical problems of foreign-body extraction, the advantages of small tubes are not generally realized For general purposes, such as the diagnosis of disease, finding of a small foreign body without risk of overriding, etc , the largest possible tube has great advantages, but in the working out of difficult problems of endoscopic foreign-body extractions, the small tube has advantages that make all the difference between success and failure As will be seen in Figure 11, a tube (*A*) that fills the entire lumen of the esophagus or bronchus has no lateral range of motion, while a relatively small tube (*B*) has a very useful range of movement The value of this lateral movement is realized when it is remembered that endoscopic tubes are rigid, whereas endoscopic instruments other than tubes are necessarily long and slender, hence the distal ends are not susceptible of a useful degree of lateral movement The forceps *C* cannot be moved with any useful degree of control from *D* to *E*, whereas the forceps *F* can be energetically moved from *G* to *H* by lateral movement of the tube, *B*, because of the smallness of the endoscopic tube, *B*, relative to the esophagus, bronchus or trachea, as the case may be We may say, then, that forceps in a large tube have no useful lateral range of movement, while tubes small in diameter relative to the diameter of the esophagus or bronchus have a lateral range of movement that is in some cases indispensable to success

Motion of Foreign Bodies in the Bronchi—An important factor which must be always in the mind of the endoscopist in working out the solution of a mechanical problem of foreign-body extraction is that the foreign body is never still a moment The movements are bechic, respiratory and pulsatory All of these movements in many cases greatly increase the difficulties of removal, in other cases the movements can be taken advantage of to assist the bronchoscopist An instance of the latter may be cited in the case of a long foreign body, such as a pin, completely hidden in a small bronchus into which the bronchoscope cannot enter but from which the point of the pin may be protruded during bechic, respiratory or pulsatory movement (Fig 10) More often, however, these movements are a great hindrance not only by the fact

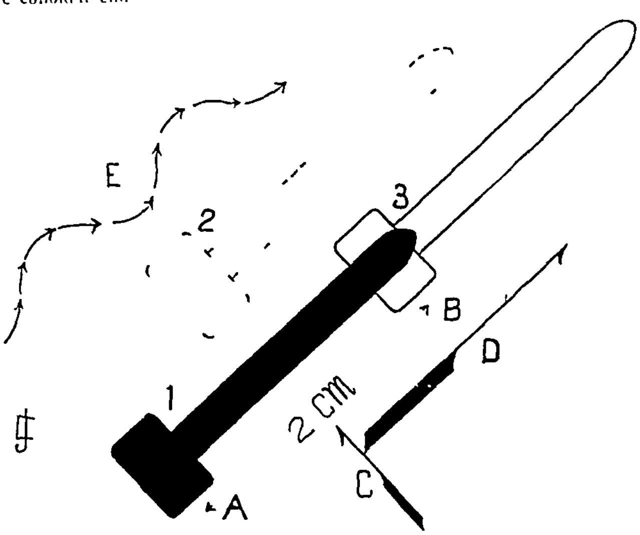

Fig 3—Schema illustrating the normal respiratory and pulsatory movement of the bronchi along with bodies contained therein There is also in case of bodies free to move, a movement of the foreign body with relation to the invaded bronchus during cough respiration, etc

that they keep the foreign body in motion, but that they all tend to bury the point of sharp pointed objects The respiratory and pulsatory movements are really in many planes, but the chief movements noticed by the bronchoscopist in all cases of foreign bodies in the larger bronchi is the to-and-fro motion toward and from the bronchoscope, chiefly in the bronchoscopic axis Advantage can be taken of this movement so to place the bronchoscope that the point of a pointed foreign body may enter the tube mouth In doing this it is very necessary to remember that the recession of the foreign body will withdraw the point out of the tube mouth unless the tube mouth is, at the proper moment, inserted far enough down over the foreign body This maneuver concerns foreign bodies whose points are free when first approached or have been freed as the first stage of the solution of the mechanical problem In addition to the more or less axial movement of the foreign body there are also a number of lateral movements, though these may be more or less hindered by some degree of opposition on the part of the bronchoscope

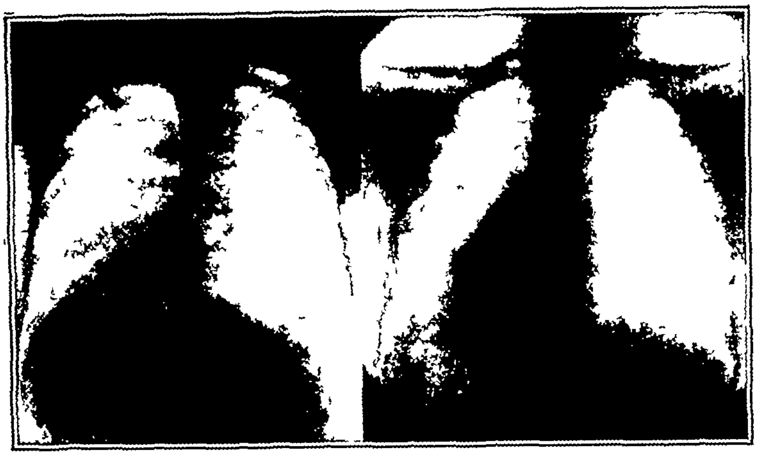

Fig 4—Roentgenogram showing obstruction of the left inferior lobe bronchus, by a Greek peanut (pistachio) shell, in a girl of 8 years When such a shadow is seen we may know that we shall have to deal with a foreign body fitting tightly and corklike in a bronchus There is shown compensatory emphysema of the right lung and also of the left upper lobe The right hand roentgenogram shows the disappearance of the triangular shadow after the removal of the pus and the obstructing foreign body, by bronchoscopy, without anesthesia, general or local (Plate made by Drs Johnston and Grier Author s case)

Fig 5—Shell of pistachio nut removed by per oral bronchoscopy without anesthesia The broad surface was found presenting requiring version to present an edge for seizure

Dr George C Johnston thus describes the various movements as seen fluoroscopically in a case of the author (Figs 1 and 2)

> The foreign body, which is 1 cm in diameter by 3 cm in length, is observed to be in constant motion The foreign body was seen to move 2 cm up and down at each excursion of the diaphragm The excursions of the foreign body are downward and outward, upward and inward In addition there is a constant lateral motion of the foreign body synchronous with the cardiac impulse The foreign body is never at rest The least amount of motion is found at the instant of full inspiration

These movements I have endeavored to represent schematically in Figure 3 They are represented in one plane only It is necessary to remember that there is a similar movement, though of less excursion, in many other planes

PROCEDURE

The various steps in the solution of the various mechanical problems of foreign-body extraction, as practiced in the author's clinic, are as follows

1 Roentgenographic study
2 Preliminary working out of a mechanical problem, based on the probabilities as deduced from the Roentgenographic study
3 Endoscopic study

Roentgenographic Study of Mechanical Problems of Endoscopic Foreign-Body Extraction—The marvelous advances in roentgenography have wonderfully simplified the solution of mechanical problems of the disimpaction and removal of foreign bodies The roentgenologist now usually produces a roentgenogram which shows not only the foreign body but sufficient outlines of the bronchi to enable the endoscopist to formulate a plan of disimpaction and removal that will be correctly based, according to the experience in the author's clinic, in about two thirds of all cases in which the foreign body is opaque to the ray In case of foreign bodies not opaque to the ray, their presence can often be determined almost certainly from the visible pathologic sequelae, yet this does not aid in the solution of the mechanical problem further than to indicate *in certain instances* (Fig 4) that complete obstruction of a bronchus means a tightly fitting, corklike impaction of the foreign body in the invaded bronchus In all cases roentgenographic study should include an anteroposterior and a lateral roentgenogram In some instances aid will also be obtained from a roentgenogram taken in the quartering lateral position, but in no instance should this take the place of the lateral, and in any case great care is necessary to prevent the quartering roentgenogram from confusing the endoscopist's mental conception of the position of the foreign body as gained from the anteroposterior and the lateral roentgenogram, taken as nearly as possible on planes perpendicular to each other Fluoroscopy cannot take the place of a roentgenogram, because, as a rule, the trachea and main bronchi cannot be seen on the fluoroscopic screen, and many bodies of borderline opacity are visible roentgenographically though invisible fluoroscopically

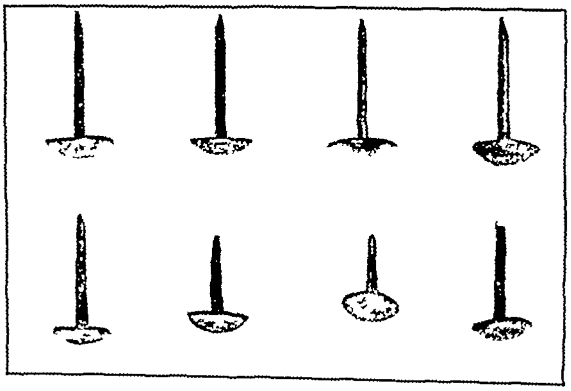

Fig 6—Upholstery tacks from the bronchi (eight cases) The removal of these presented the mechanical problem of the mushroom anchor

Prearranged Plan—Given good lateral and anteroposterior roentgenograms showing the size, shape and position of the foreign body, a knowledge of the duration of the sojourn, and a previous experience with a similar foreign body, a preliminary plan of extraction can be worked out, and in most cases such a plan will be found successful If, however, the intruder has been injudiciously pulled on, preliminary plans are usually useless, nothing but local endoscopic study will avail

Endoscopic Study—The region of the foreign body should be approached carefully so that the tube mouth or secretion swabs shall not touch the foreign body until after the size, shape and, particularly, the position of the intruder relative to the bronchial wall, are studied Careless swabbing may force the foreign body downward In the larynx, to justify an endoscopic study before seizing the foreign body, the patient must be in the author's "low head" position, so that if dislodged the intruder will not drop downward into the deeper air passages In using this position the author has a number of times released and regrasped a foreign body in the work of disengaging the point or otherwise solving the mechanical problem presented by the removal of the foreign body with the least possible trauma

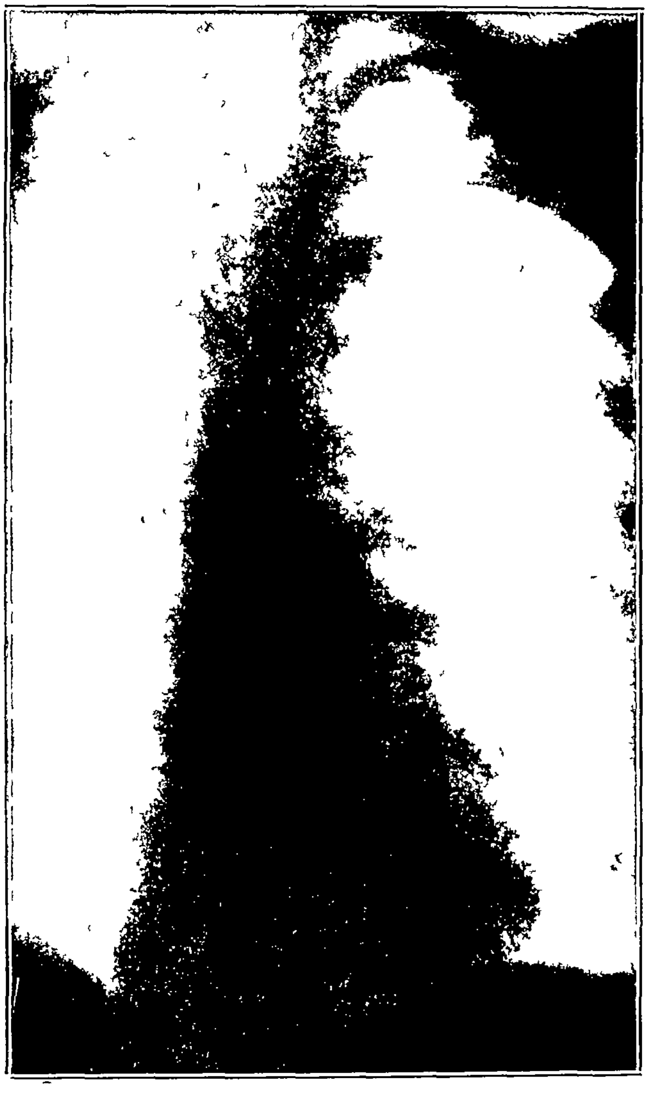

Fig 7—Roentgenogram showing a bit of wire from an egg beater in the esophagus where it had lodged while the patient was eating custard pie The hooked ends do not show because the bends are in the sagittal plane

MECHANICAL PROBLEMS

Objects Presenting a Thick Conical End—These often present great difficulty of grasping because the forceps are prone to slip both sidewise and longitudinally Forceps whose jaws are slightly cup-shaped have less tendency to slip sidewise, and those with properly made teeth will usually hold if the jaws are sufficiently far down on the object, as for instance was done in case of the foreign body illustrated in Figure 2 This is not often easy to do in case of thick foreign bodies because the proximity of the bronchial walls prevents proper expansion of the forceps' jaws The difficulty is much increased if the intruder has been in situ sufficiently long to permit of swelling of the superjacent bronchial mucosa, and the difficulties may be enormously increased by trauma of previous attempts

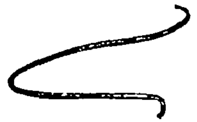

Fig 8—Wire removed by peroral esophagoscopy from the esophagus of a woman aged 57 years Removed by peroral esophagoscopy without anesthesia general or local The object is turned partly edgewise to show the hook shaped ends which presented the great difficulty in removal

Irregular Objects—These frequently present in such a way that they require turning so as to present a favorable surface for the grasp of the forceps For instance, the peanut (pistachio) shell (Figs 4 and 5) presented its concavity toward the tube mouth The shell was turned so as to present its edge for the grasp of the forceps Watermelon seeds (Fig 12) in many cases require to be thus turned Version is one of the most frequently required procedures in the solution of endoscopic mechanical problems

Sharp Pointed Bodies—All sharp-pointed, more or less straight bodies, such as needles, pins, nails, tacks, etc, have strong tendencies (1) to become embedded at the point, (2) to become transfixed crosswise, and (3) to work lower and lower into the air passages by a ratchet-like action The mechanical problems of their removal have been elsewhere gone into quite extensively by the author and need not be reconsidered here In general, however, it may be stated that the pulling on such bodies almost invariably results in crosswise fixation or fatal laceration of the bronchi, with failure to remove In all cases the position of the foreign body should be carefully studied with a view to getting the point disimpacted and into the tube mouth before any traction whatever is made Quite frequently the disengaging of the point requires the pushing of the foreign body downward so as to withdraw the point from the wall in which it is embedded by bechic efforts at expulsion in the case of the air passages, and by the pressure of food in swallowing in the case of the esophagus

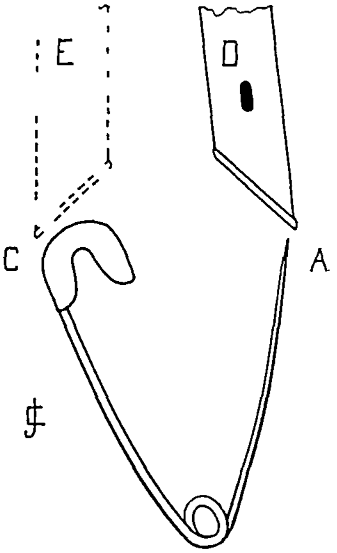

Fig 9—The problem of the safety pin Twenty seven safety pins have been endoscopically removed from the larynx trachea bronchi and esophagus in the author's clinic, by this and other peroral endoscopic methods

Transfixed Foreign Bodies—Both points being embedded, these bodies usually require very careful handling, otherwise attempted removal will be quickly fatal They are quickly and safely dealt with by the methods elsewhere described, which have been uniformly successful in sixty-four cases Many of the cases presented other problems in addition to the problem of transfixion

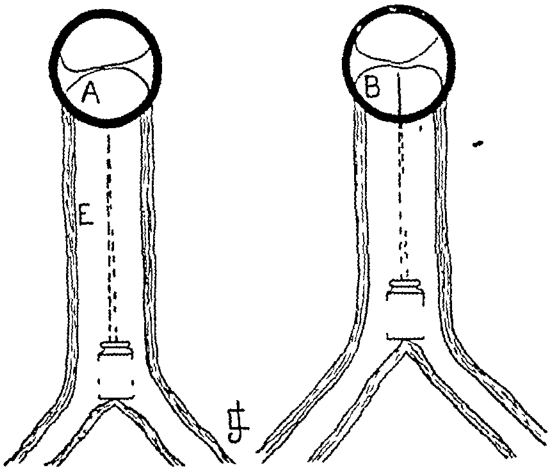

Fig 10—Schematic illustration of bechic aid in revealing a foreign body in a bronchus The dental instrument, *E*, was entirely contained in a small branch bronchus so as to be entirely invisible to the broncho scopist looking down the stem bronchus, *A* When the patient coughed the altered position of the bronchi caused the point of the dental instrument to emerge into the lumen of the stem bronchus as shown at *B* whence it was easy to remove with forceps

Safety Pins, Open, and Point Upward—The most important utilization of the roentgenographic study is for the endoscopist to get a mental picture of the position of the foreign body with reference to the approach of the endoscopic tube For instance, if the esophagoscopic tube is allowed to approach the foreign body without any previous study of the problem, it will usually, in the case of safety pins, present to view first the keeper end of the pin as shown at E, C, Figure 9 If, however, the endoscopist from previous study knows that the point *A* is, for instance, outward to the left, he bears in that direction with his tube mouth, as shown at *D*, with the result of bringing into view the point, *A*, or, if this is buried, the shank of the pointed end as near as possible to the point This enables the endoscopist to solve the safety pin problem in one of the simplest ways, by seizing the pointed end of the pin, *A*, drawing it within the tube mouth, when traction will be relatively safe, as compared to traction on the end, *C*, which will almost invariably prove fatal from perforation of the esophagus, by the point, *A* Practically the same problem is presented when a safety pin has lodged in a bronchus, especially if, as in one of the author's cases, the point, *A*, had entered far into a lateral branch In one of the author's cases, the safety pin had lodged in the right bronchus with the point of the pin projecting into the right upper lobe bronchus completely hiding from view all of the shank, *A* The problem was solved by closing the pin by use of the well-known tilting ring and push fork instrument In case of esophageally lodged safety pins, the best method in the author's experience has been the one that in the Pittsburgh clinic is called "endogastric version" We have had altogether 27 cases of safety pins, 16 being in the esophagus, 2 in the trachea, 1 in the bronchus, and 8 in the larynx Of the esophageal cases 5 were closed before removal, 4 were removed by protecting the points with the tube mouth (Fig 9), and 7 were removed by endogastric version All of the patients were discharged cured Our "follow up" system discovered that in one case the child was taken suddenly ill about ten days after leaving the hospital, and died, the exact cause of death not being determined In this case the pharynx and larynx had been found, at esophagoscopy, to have been very badly lacerated from the attempts of the parents with their fingers to remove the safety pin The esophagus showed trauma caused by blind efforts with forceps and bougie before coming into the clinic No postmortem was made

Upholstery Tacks—These (Fig 6) usually lie point upward with the head buried in swollen mucosa, presenting the "mushroom anchor" problem, the solution of which has been elsewhere described It may be stated that our recent cases have brought the total up to eight cases

Double-Pointed Tack—One of the most difficult problems to solve is that of the double-pointed tack, the points being upward and buried in the swollen mucosa In the esophagus the most serviceable method is that of endogastric version, as with safety pins In the air passages version, is much more difficult, but can be accomplished by very patient work The technic has been previously described[1] We have had six cases of fence staples Two were in the trachea, one in the right bronchus, one in the left bronchus, and two in the esophagus All of these were removed by endoscopic version Five patients made a prompt and uneventful recovery One patient, who had been subjected to ill advised traction previous to admission, was suffering with a mediastinal emphy-

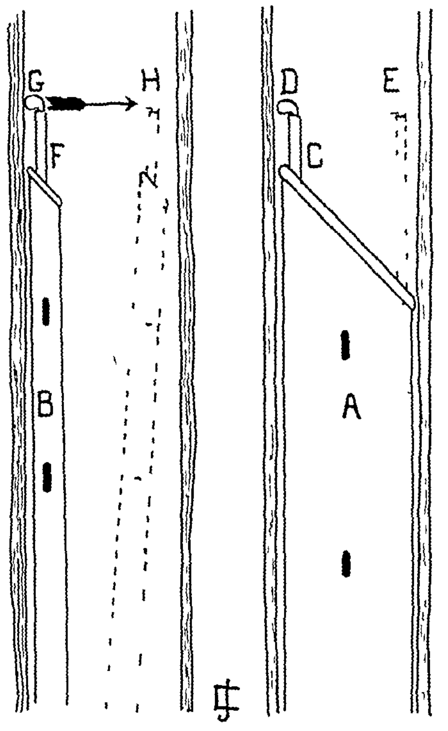

Fig 11—Schema showing advantage obtainable by the use of tubes of relatively small diameter Sidewise movements of forceps can be executed with a small tube, *B* that are impossible with a tube of large relative diameter because the thin flexible forceps, incapable of lateral movement can be forced sidewise by the rigid endoscopic tube if the latter is of relatively small diameter

sema, which rapidly proved fatal In another case a double pointed tack escaped into the pleura, whence it was removed by external operation

---

[1] Jackson Chevalier A Fence Staple in the Lung THE JOURNAL A M A, June 5, 1915, p 1907

Hook-Shaped Bodies —Hook-shaped bodies, such as artificial dentures with retaining hooks, bits of metal, wire, etc, present great potential dangers if injudiciously pulled on Usually they require pushing to withdraw the point of the hook A very difficult problem was presented by the very sharp, hook-shaped point of the wire, Figures 7 and 8 The sharp, hook-shaped extremities were liberated by sidewise movement and then were gotten into the mouth of the esophagoscope, where they were prevented from harming the esophagus during withdrawal Traction on the part first presenting would have resulted in perforation into the mediastinum

A few words on prophylaxis may not be amiss here The presence of this sharp-pointed piece of wire in this woman's esophagus points to the carelessness of using an old broken egg beater in making the custard pie, the swallowing of a piece of which led to the accident The frequency with which we have removed small bits of bone from the air and food passages of children and adults points to almost criminal carelessness on the part of the butcher shop and kitchen Pins and needles should not be kept in the kitchen, nor should they ever be held in the mouth while dressing or sewing or at any other time The fifty pins, needles and similar pointed objects we have removed point to avoidable accidents Children should be taught not to put in their mouths anything not fit to swallow The author has collected from the public press in a single year forty-three cases in which children died from the lodgment of a foreign body in the larynx, death occurring before a physician arrived All toys should be regularly inspected for loose small parts that might be put in the mouth Coins, poker chips or other small objects should not be used for teething rings Workmen should have some carrier other than their mouths for tacks, nails, screws, etc No one should go to sleep with an artificial denture or any other loose object in his mouth Even an undissolved tablet has been known to cause death by asphyxia The fact that, thanks to bronchoscopy and esophagoscopy, such objects can be almost invariably removed through the mouth without operation does not excuse the ignorance or carelessness that permitted the accident to occur

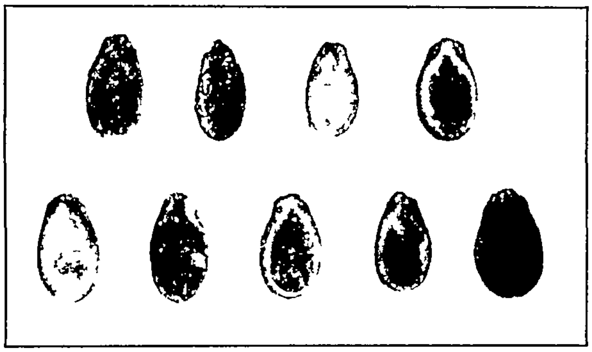

Fig 12 —Watermelon seeds removed from the bronchi of children (nine cases), by peroral bronchoscopy, without anesthesia general or local Some of these required version so as to present an edge for the grasp of the forceps

Tightly Fitting, Corklike Bodies —These are especially apt to be associated with an annular edema of the bronchi which prevents a proper spread of the forceps' jaws Two very successful methods of dealing with the problem have been previously published Briefly described, one is by means of the lip of the bronchoscope making sidewise pressure to permit the insinuation of the hook below one side of the foreign body The hook is then turned and the foreign body pulled on sufficiently to withdraw it above the annular edema, where it can be seized with forceps In the other method, strong springlike forceps' jaws, which push back the annular edema in one plane, are employed These two methods have been successful in dealing with this problem in fifty-two cases, without mortality

Soft, Friable Bodies in the Bronchi —The essential difficulty in most of these cases is to take sufficient hold with the forceps to permit the withdrawal of the body and yet not such a firm pressure as to crush the intruder While the fragments of these bodies may be coughed up if comminuted, a much more likely result is to have fatal multiple abscesses with a septic bronchopneumonia as the result of aspirating the fragments into different portions of the lung We have had sixty-two cases of soft friable bodies, including nut kernels, maize, and various vegetable substances The foreign substance was removed in all of the cases There was no operative mortality, but our "follow up" system discovered that two of the patients had died a number of weeks later of septic pneumonia In both of the cases the foreign body was a peanut kernel No postmortems were obtained, but it seems probable that some fragments of kernel remained behind either from the breaking off of a fragment when grasped by the forceps, or the foreign body might have been multiple in the first place It is also possible that the very violent septic bronchitis which is found in practically all peanut cases may have been more than the child could combat

Bones —The problems of dealing with bones are concerned chiefly with their shape, and these have already been mentioned in connection with pointed objects, transfixed objects, etc Of bones in the larynx, trachea, bronchi and esophagus we have had forty-seven cases The bone or bones were removed in all cases No anesthetic, general or local, was used except in two cases where the bone was of enormous size and very sharp Here the relaxing effect of anesthesia was deemed necessary for safety, to prevent the esophagus being lacerated by spasmodic gripping of the foreign body on removal In all of the cases of bones, the patients, with a single exception, made a perfect recovery The exact cause of the one death, some days later at the patient's home, was undetermined The patient had a nephritis, though this was stated not to have been the immediate cause of death

Disklike Objects —These usually present no difficulty unless they are somewhat saucer-shaped and wedged in swollen mucosa and transversely placed In this case the lip of the bronchoscope is used to make a slight crevice or dent in the swollen mucosa at one part of the disklike object so that an edge can be drawn upward to be seized by the forceps Pins, sharp points or serrated edges, on disks, complicate the problem and require rotation so as to prevent laceration of the tissues during withdrawal of the foreign body

In sixty-four cases, buttons, coins, skirt weights and similar disklike objects, including a poker chip, have been removed in our clinic without anesthesia and without mortality

THE POSSIBILITIES AND LIMITATIONS OF NONSURGICAL BRONCHOSCOPIC TREATMENT *

ROBERT F. RIDPATH, M.D.
PHILADELPHIA

GENERAL CONDITIONS OF PATIENTS REQUIRING BRONCHOSCOPIC EXAMINATIONS

The patients and their conditions will vary as does the rainbow. They are usually those who have been treated from one month to a number of years by many different doctors. The majority are more or less emaciated, from the persistent cough and the knowledge of something wrong in their chest for which they have received no relief. Some are sent direct by their physicians; others, having developed the dispensary habit, going from one hospital to another, finally hear of your wonderful bronchoscope and through curiosity as much as the desire for a cure come into your hands. Dependent on the special condition of our patient, we find the general condition. Hence, the asthmatic with his barrel-shaped chest; the tuberculous laryngetic, with hoarse voice and almost continuous expectoration of frothy consistency; the hysterical, who seemingly imitates all or any one of the many symptoms of disease. Generally speaking, however, they are perfectly willing to undergo any examination or instrumentation, to have a correct diagnosis made with the possibility of a cure.

POSSIBILITIES OF DIAGNOSIS GREATER THAN BY OTHER MEANS

That the routine use of the bronchoscope is of invaluable advantage in obscure diagnosis is being demonstrated constantly. Tumors or growths outside of the trachea or bronchial tube pressing and occluding the lumen are of frequent diagnostic occurrence. Calcareous deposits on the tracheal rings are as easily seen as though they were on the finger nails. False membrane of diphtheritic or other origin is found and removed with entire relief from the offending symptoms. Papilloma or other growths causing cough, dyspnea, reflex spasms of unwarranted severity, and either mechanically or clinically producing coughs, rales, expectorations, hemoptysis, malnutrition with greater susceptibility to other or all diseases are diagnosed and removed. Ulcerations from various causes, tuberculous or otherwise, are seen and medical agents applied. Strictures are dilated, asthma and tracheitis treated, all of these and many more are to us an open door through which we see many more possibilities in the future.

TREATMENT OF DISEASES AND CONDITIONS BY LOCAL MEANS

Tracheitis, or tracheal bronchitis, is one of the most frequent conditions we come in contact with. Like bronchial asthma, it appears in two forms: first, as highly inflamed or mucous-covered areas of mucosa, extending around the whole lumen of the bronchi, or as patches along its walls, varying in size from a large pinhead to from one half to an inch in length; second, we may find a dry condition, the secretions, if any, having formed hard crusts or scales of a dark or greenish hue. We are rather inclined to think the second condition is simply a later development of the first. It is within the realm of possibilities to follow the course of the disease from the original infection with the organisms producing the irritation, Nature doing her part by sending leukocytes in abundance to stop the offending invasion; then tracing the outpouring of these through the mucosa with serum, constituting in this way secretion, with the corresponding tuberculous cough and expectoration. If resolution takes place, our patient is well; if not, the mucosa, as a result of the drying of these secretions and the almost continuous cough, breaks down in places and ulcerations form.

The etiology is many sided. It may be due to the occupation, as in the case of a stone or marble worker, or workmen breathing the fumes from iron molding or various vapors of acids; chauffeurs who drive continuously, inhaling quantities of dust. Bad hygienic surroundings may be the cause, or it may be produced by a condition of the upper air passages necessitating mouth breathing, in which we have lack of proper filtration, warmth or moistening of the inspired air; it may be due to sinus involvement, the continuous heavy bacteria laden discharge inflaming the pharynx and continuing by gravity or osmosis, finally reaching the larynx and trachea.

The treatment naturally divides itself into two methods: that appropriate for the first condition and that suitable for the second. We have found applications of glycerite of tannic acid, applied by tampons, the ideal treatment of the first division. These are to be used every other day, the whole lumen of the trachea or bronchi to be carefully gone over and painted. For the later development several therapeutic agents suggest themselves. We must first remove all incrustations, touching the underlying ulceration with silver nitrate, or other silver preparation, or a 10 per cent alcoholic solution of iodin. The dry, reddened membrane responds best to stimulation by the ultraviolet ray. This is applied by means of a vacuum through the bronchoscopic tube, giving not more than one-sixteenth inch spark at any time. As you all are aware, high frequency current is one of our most refractory agents, always wishing to go the long way to a given point instead of the short, and for this reason we have had considerable trouble in perfecting a properly insulated applicator for its use. The ultraviolet ray or spark when applied in this manner stimulates the mucosa to greater activity and acts as a tonic to the underlying arterioles and nerve filaments, dilating the blood vessels to their proper caliber. I have stated the length of spark on account of the great number of electrical machines on the market, with their various ratings of voltage and amperage, thus confusing and complicating the treatment. The current acts in two ways, a one-thirty-second to a one-sixteenth inch spark acting as a stimulant, whereas a larger, stronger spark is destructive in character.

Bronchial asthma can be traced, diagnosed and treated by bronchoscopic means in a surprising number of cases, although all available literature on the subject clouds the causative factor of this condition with many theories. If we expect to find the same clinical picture in all cases, we will *fail utterly*, for just as patients differ in all other characteristics, so their bronchial picture varies. As Jackson[1] has truly said, in order to get an accurate picture, it is necessary that the examination be done without any anesthesia, general or local, in at least one of the sittings with each patient, so that the bronchoscopic picture shall not be altered by the application of the anesthetic The writer reported a case[2] the causative factor of which was a papilloma situated on the carina, and the removal of which gave immediate relief and permanent cure Another case was found to have its exciting cause in quite a large ulceration between the second and third bifurcation on the right side, the treating and healing by bronchoscopic means was followed by entire relief of the patient's asthmatic attacks In the majority of cases, however, we have found the mucosa of the trachea and bronchi red and swollen, here and there covered with stringy, mucilaginous secretion, the removal of which, in quite a number of cases, disclosed ulcerations I have never seen, as Freudenthal[3] records, the appearance of a scarlike mass obstructing the entire lumen of the bronchus, but have frequently seen the lumen partially occluded by such masses I would divide the cases of bronchial asthma into two general classes those in which we have an inflamed, dry mucosa, which may or may not have a local lesion in the tubular air passage, and those in which the mucosa is inflamed and swollen, causing a lessening of the general lumen of the trachea or bronchi, and in which the secretion is copious, the primary factor may or may not be locally situated Dr James Adams has justly pointed out that asthma in most cases is essentially a toxemia and no treatment can be successful without recognition of this fact If we take into consideration the many elements which may enter into the morbid anatomy of asthma, such as the nasal passages, alimentary tract, blood, urine, malformation and toxemia from scores of causes, we can readily see that the bronchoscopic appearance of the mucosa of the respiratory tubes also must vary according to the exciting factor When all other possible causes have been eliminated and no apparent reason assigned, bronchoscopic treatment may be resorted to with numbers of cures reported

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty-Seventh Annual Session of the American Medical Association, Detroit, June, 1916.

[1] Jackson: Pectoral Endoscopy and Laryngeal Surgery, p. 478.

Ephraim[4] reports six patients cured, eleven improved and twelve not influenced by endobronchial treatment He used a mixture of novocain, epinephrin, and normal salt solution, later reporting 133 patients treated with a spray of epinephrin and novocain with excellent results Greenwald[5] reports good results following repeated applications of 1 10,000 epinephrin

Personally, in the treatment of the conditions described in the first division, I proceed as follows If the trachea is dry or inflamed, the proper treatment is to build up the mucosa as any other mucous membrane in the same condition We first relieve the congested arterioles of the excessive blood by spraying with 1 5,000 or 1 10,000 epinephrin in normal salt solution, after which may be applied by local tampons equal parts of compounded tincture of benzoin and boroglycerid, or a silver solution, or a spray of pure liquid petrolatum with 1 per cent ichthyol applied to all diseased areas This should be repeated in three days and continued at that interval for five or six times to note any effect If the case is one of the second variety, the secretions must be removed by vacuum, all masses of mucus removed, the ulcers treated with silver nitrate, 10 per cent, and a local application of glycerite of tannic acid to the mucosa This should be repeated twice weekly

Papilloma of the larynx in children occurs in two forms In one form the growth disappears spontaneously, in the other, surgical or other means are required That papilloma occurring in children is more frequently cured spontaneously there can be no question Of those patients requiring treatment, I am permitted in this paper to speak only of other than surgical means, of which there are four methods of treatment (1) fulguration, (2) radium, (3) Roentgen radiotherapy, and (4) medicinal agents

Fulguration by means of high frequency current is unquestionably a curative agent to be considered in this condition and if persisted in for several treatments will effect a cure, the only disadvantage exists in the growths which lie under the cord, their position being almost inaccessible for fulguration treatment Harmon Smith[6] reports exceedingly satisfactory results by this means

Radium in every case thus far reported has not only effected a cure, but seemingly prevents recurrence

Roentgen radiotherapy has never been used to any great extent, but should have a curative effect if properly given I am rather inclined to believe that a series of applications of the Roentgen rays will limit the frequency of return in those cases which have had operative treatment

Delevan uses applications of alcohol, starting with a 50 per cent solution and increasing the strength as the treatment progresses We must, however, be exceedingly careful not to have the applicator dripping E L Jones has had excellent results from a saturated solution of salicylic acid in alcohol

I have used fresh pineapple juice in one case with entire destruction of the growth, the action of the juice seeming to shrivel the papilloma, the only disadvantage is in the number of applications necessary, requiring a dozen or more I do not think tracheotomy is necessary before using any of these applications, but all medication must be applied direct to the papilloma and not indiscriminately to any and all of the laryngeal mucosa Papillomas in adults are on the whole more amenable to treatment than similar growths in children and decidedly less liable to return

It is also well to remember that benign growths proliferate on the surface and do not infiltrate

The significance of tuberculosis of the larynx, trachea and bronchi is too well known and appreciated by the profession to need emphasis or repetition With the aid, however, of bronchoscopic methods more light and quicker diagnosis and treatment are made possible In practically all literature obtainable tuberculosis of the larynx and trachea are considered secondary to pulmonary involvement, and yet case after case coming under my care, when examined bronchoscopically have both clinically and microscopically been diagnosed tuberculosis without showing any pulmonary lesions, either clinically or by means of Roentgen-ray examination Granting that the lung tissue is possibly better soil for the growth of the bacillus and the trachea and larynx become involved secondarily, I am unable to see any reason why the interarytenoid tissue, the cartilages or the mucous membrane could not be primarily infected, extension and invasion of the lung tissue taking place secondarily

Dr George Wood in his admirable article has clearly demonstrated the frequent involvement of the tonsils with tubercle bacilli, also that the tonsils act as a portal of entry for the disease into other portions of the body

---

[2] Ridpath R F Laryngoscope 1914, **24**, 942
[3] Freudenthal New York Med Jour, June 24, 1911
[4] Ephraim Monatschr f Ohrenh 1913
[5] Greenwald Munchen med Wchnschr, 1913

[6] Smith Harmon Laryngoscope 1913 **23** 1029

As the tonsil is so frequently involved, it does not require such a vivid imagination to reason that the same infection might, and does, occur primarily in the larynx and trachea, the only reason of our inability to properly diagnose the cases has been due to ourselves, and the close simulation of beginning tuberculous laryngeal inflammation to simple acute or chronic laryngitis

With the routine use of the bronchoscope, I believe that another era has dawned for diagnosing and treating tuberculosis in its incipiency According to Casselberry[7] one of the earliest and most destructive of the initial tuberculous changes in the larynx and one which may precede by years any more active development is the mammillated hyperplasia commencing at or near the subglottic portion of the base of the vocal process and gradually marked by a furrow in the vocal angle This later ulcerates into vaguely outlined margins with mouse eaten edges, their base covered with granulation tissue Infiltration and edema may now occur with extension of the disease St Clair Thomson reports 50 per cent of those who die from tuberculosis show laryngeal involvement at postmortem examination, and further states that in ninety-nine out of 178 patients with laryngeal tuberculosis treated in the past three years, the disease was either arrested or improved Brull reports 58 per cent of the patients clinically cured and of these, 31 per cent remained cured While the local treatment for this condition affecting the epiglottis and larynx can be pursued by the direct bronchoscopic method, the suspension laryngoscope of Killian or Lynch is much to be preferred, affording the operator both hands free and close range examination The treatment is to destroy the local lesion either by surgical means, with the curet or by electrically or medicinally cauterizing the area Patients must be cautioned about the resulting edema from these treatments and instructed of its dangers I would suggest to treat only a small portion of the infection at one sitting, thereby reducing the danger from edema If the ulceration occurs in the trachea or bronchial tree, cauterization may be done by beaded chromic acid or trichloracetic acid

Catarrhal hypertrophies of the mucosa appear as swollen, inflamed, spongy areas extending into the lumen of the trachea or bronchi and lessening its diameter The secretion is usually found to be very tenacious and hard to remove The treatment varies with the condition present, from the use of glycerite of tannic acid, or a 2 per cent solution of silver nitrate, to the application to the swollen areas of chromic acid, used as a bead on an applicator

Bleeding from any of the arterioles of the mucosa is easily seen It may originate from a tuberculous lesion, malignancy or aneurysm and the treatment should be instituted according to the condition

Stricture or stenosis of the trachea or bronchi occurs mainly from outside sources Goiters, enlarged thymus, tumors of the esophagus, mediastinal or thoracic tumors and aneurysm may produce it, and with removal or treatment of the original cause we have a decrease or a cure of the stenosis

Syphilis of the tracheobronchial tree may also occur In spite of the frequent involvement of syphilitic lesions in the larynx, the finding of lesions in the lower air passages is a rarity These lesions may be inflammatory, ulcerative or gummatous A therapeutic or Wassermann test is, however, necessary for confirmation and exclusion of tuberculosis

For vocal nodules, Wylie recommends very highly the use of the galvanocautery point Great care, however, must be employed in its use A saturated solution of magnesium sulphate repeated every other day or very small applications with trichloracetic acid will practically always give us the desired cure

Cystomas, according to Jackson, have been known to be cured after galvanopuncture, but he also states that we must be sure to destroy the sac

LIMITATIONS

As all procedures must necessarily have their limitations, so we meet with finitude in bronchoscopy Patients with valvular heart disease, those having any cardiac lesions with failure of compensation, are practically barred from a bronchoscopic examination, first, because of the excitement caused by the examination, and second, by their inability to stand the local anesthesia Patients with long-standing cases of asthma, with the typical barrel-shaped chest and the abdominal breathing, more or less constant cough, dyspnea, thick tenacious mucus and expectoration do not stand the examination well even if the tube can be passed at all They are also very susceptible to cocain and the examination of these patients is almost impossible without its use on account of the chronic inflammation of the membrane People with short, thick necks with their inability to flex the head on the back of the neck are numbered among the class of bronchoscopic impossibilities Arthritis occurring in any vertebral articulation precludes examining the trachea In serious cases of dyspnea the application of cocain with the instrumentation would be extremely dangerous Dyspnea may increase if the larynx is stenotic before operation, necessitating tracheotomy Ankylosed jaws naturally would make an examination impossible Aneurysm might not only produce pressure, with a corresponding convexity to the tracheal circumference, but with the increased blood pressure accompanying it This condition demands great caution, not to speak of the danger of rupturing the aneurysm, an accident which occurred in one of Collier's cases Apoplexy and arteriosclerosis are contraindications Goiter if of sufficient size to press on the tracheal rings or cartilages will be sufficient mechanical obstruction to limit an examination Idiosyncrasy to cocain may induce toxic syncope Serious hemorrhage could occur only in a hemophiliac

---

The Medical Mind—Our environment has often caused serious rifts in the brotherhood because, above all things, we are human We are critical, skeptical credulous Let some toiler and earnest worker discover a truth and give it to the world Its *reception makes interesting* reading and causes us to wonder at the strangeness of the human mind Harvey announces the circulation of the blood, Jenner gives vaccination to us Morton gives us anesthesia, Oliver Wendell Holmes shows us the cause and prevention of puerperal fever All these and innumerable others are met by ridicule, angry opposition and abuse It is not that the medical mind does not welcome the truth It is that we are slow to see it—that we have been thinking in grooves for so long that it takes years before a new manner of thinking can be developed—James M Putnam, M D, Address before Buffalo Academy of Medicine

THE POSSIBILITIES AND LIMITATIONS OF SUSPENSION LARYNGOSCOPY*

ROBERT C LYNCH, M D
NEW ORLEANS

Suspension laryngoscopy as a procedure is so new that the proverbial pendulum has hardly begun to swing in either direction In the first place, are you entirely satisfied with the instruments as they are shown to you at this time? Is it probable that the last word has been spoken in this regard? I may answer this by saying that I am constantly looking for a more simple instrument than the one I have been using

It would seem that the mechanics involved is on a sound foundation and the principle as proposed by Killian is faultless, yet modern ingenuity may change our method considerably

As we view it today, suspension laryngoscopy is not to be practiced successfully with any instrument designed primarily to sell for $10 The act of suspension is not a simple, safe operation and if we elect to suspend our patient with an instrument that is flimsy, fragile and too dainty to bear the burden, we shall lay the patient open to the possibility of a serious termination and ourselves to criminal negligence

You must bear in mind that in order to convert the curved road from the teeth to the vocal cords, with the mouth wide open, into a straight path, there is required a considerable amount of power and a certain amount of muscle relaxation, the one bearing a direct proportion to the other, and in addition must be considered the possible variations in normal anatomy designed apparently to defeat your purpose

This means that one must use more power than the uninitiated realizes and must apply this in a manner that is perfectly safe in its every detail There are required rigid, strong, well-built instruments which will withstand any strain to which they are subjected

It is an easy matter to view the larynx through a Jackson or Mosher spatula, and the application of either model in trained hands is practical without pain or danger to the patient, and not uncomfortable to the operator In the use of this, however, one hand is busy with the spatula, and whatever further is done must be accomplished through a closed or split tube

With suspension the chief advantage is in seeing the parts in their entirety through a wide-open mouth and in obtaining a view limited only by the boundaries of nature, with no part of the instrument in the field, and with both hands free to work as the indications require One examines more minutely and by direct vision selected areas, using one or both hands to acquire the view One sees plainly before him the entire interior of the oral cavity, the mesopharyngeal and hypopharyngeal spaces, the mouth of the esophagus, and the posterior and interior aspects of the larynx and trachea by such a broad view as is impossible to acquire by any other means For instance, to look into the ventricles of the larynx either by my tilting mirror or directly, or to see the inferior surface of the vocal cords, either by a mirror placed below them or by actually lifting the cord so as to bring the under surface into view is a possibility under suspension only

To study the larynx in health and disease by the tactile sense is an entirely new experience in this field For one who has been trained in the old school of mirror, tongue napkin, applicator or forceps to be permitted to sit before his patient with the larynx entirely exposed in such a manner that no part will be lost sight of, to view each detail carefully, slowly and deliberately and to have the perfect assurance that nothing that the patient can do will in any way alter or disturb the view, then to proceed deliberately to study each detail by the sense of touch and sight combined, to palpate tumor masses, to feel the extent, character and depth of ulcerated and indurated areas, to determine the progress of proliferating, inflammatory and new growth formations, to study the muscular movements of the vocal cords during respiration and phonation and to search the nooks and corners for evidence of disease must awaken in him a sense of delight and satisfaction similar to that experienced by the skilled diagnostician who palpates a stone or abscess in the pelvis of the kidney or an aneurysm of the common iliac artery, or a gynecologist who recognizes an early extra-uterine pregnancy

Now, to proceed further and to remove by dissection a tumor or cyst growing from any locality in the same manner and with the same instruments, slightly modified, as the general surgeon would select to remove a similar mass from the skin surface, to pass a bronchoscope between the vocal cords down into the trachea of an infant or young child, to remove a foreign body from the trachea by means of forceps unaided, to curet and cauterize ulcerated areas accurately without danger of injuring the normal structures surrounding the field of operation, to do a plastic operation on a selected part and to be able accurately to place stitches when and where needed, to introduce the esophagoscope or to remove from any area within the field of view a specimen of tissue for the microscope — these briefly are some of the present possibilities of suspension laryngoscopy

It must be borne in mind that the suspension apparatus is not intended as an instrument for ordinary office examination, nor is it to be used when one wishes merely to see the lingual tonsil or the mouth of the esophagus, nor will it ever replace the use of the bronchoscope or esophagoscope In fact, it is not intended to replace the ordinary throat mirror or the various direct spatulas or the tubes Its field of usefulness is, as I have tried to outline, separate and distinct from all other methods known to us

One acquires skill in its use with a little practice, but like all delicate manipulations, a certain amount of continuous practice is essential to best results For this reason if one has but a limited field or a small clinical service in which facilities are limited, the suspension will not be a valuable addition It is not intended for use in makeshift, impromptu operating rooms, with kitchen tables, ironing boards and the like for equipment

Flimsy mouth gags with sliding tongue plates, having a handle and hook attached, will not replace the carefully constructed instruments presented to you by Killian and myself So long as the principles involved remain as we now consider them, this type of instrument can yield nothing but failure to you and throw discredit on the procedure, so I caution you against them as a class

Fixed cervical vertebrae throwing the chin near the sternum or any other similar deformity which would render it physically impossible to open the mouth or convert the curve into a straight line would contraindicate the use of the apparatus

---

* Read before the Section on Laryngology Otology and Rhinology at the Sixty Seventh Annual Session of the American Medical Association Detroit June 1916

A large epithelioma at the base of the tongue with cervical gland involved and one or both pillars of the pharynx indurated would likewise contraindicate its use

In those cases in which thyrotomy and low tracheotomy have been done in persons with long necks, if the larynx seems to drop lower into the chest cavity than the normal and the resulting scar from previous operations limits the free extension of the chin, I have found it impossible to see by suspension any more than the posterior aspects of the arytenoid cartilages

Lastly, one has the privilege of discretion in the selection of his subjects for suspension, and this he is expected to practice at all times and with due regard for patient and apparatus alike

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS JACKSON, RIDPATH AND LYNCH

Dr William Bricker Chamberlin, Cleveland Just as the bronchoscope marked an advance over the older indirect method, so suspension laryngoscopy has marked an advance, but in a fairly limited field, over the bronchoscope Dr Lynch has made some decided contributions in the endolaryngeal instruments which he has devised I have used a few of them, and find them exceedingly valuable The advantages of suspension laryngoscopy must be apparent to all who have used this method The first thing that must occur to one is the advantage of this method in having the patient suspended by a mechanical device, thus leaving both hands free for any manipulation The very striking advantage of having two hands free came to me sometime ago, when in a rather short space of time I had three cases of open safety-pin in the esophagus I was able in each case to dilate the opening of the esophagus with a pair of nasal forceps, and by grasping the head of the pin and giving the forceps a turn bring the eye of the pin into view Then I grasped the eye of the pin with a second forceps, thus doing a version in the esophagus the same as we do a version in the uterus Suspension laryngoscopy is especially valuable in children It certainly has rendered the handling of the larynx in children a very successful operation Much of this work could probably be done equally well by bronchoscopy but it certainly is much easier to accomplish by means of suspension In children with suspension, a general anesthetic is necessary In the adult one may use either a general or a local anesthetic, depending on the disposition of the patient Both suspension laryngoscopy and bronchoscopy have their special fields One who has examined the hypopharynx or larynx with the bronchoscope can fully appreciate the added advantages which suspension affords You have the whole field immediately in view, and you can demonstrate this field to those who have never seen it before—men who are not experienced in the use of the laryngeal mirror I want to enter a plea that we continue to perfect ourselves in the old method of indirect examination and indirect operation Dr Lynch has well said that suspension laryngoscopy is not a procedure for the country home on the kitchen table or ironing board, nor is it a procedure for the office, it is a hospital operation Many growths in the larynx can be removed just as successfully by the indirect method as by the direct, and if any one of you had the choice between having a small papilloma of the vocal cord removed by the indirect method in a few moments in a physician's office, or going to a hospital and submitting to the discomfort of suspension, you would not be long in making up your minds There has been such enthusiasm over bronchoscopy and suspension laryngoscopy that many of the younger men have failed to perfect themselves in the old technic of indirect examination and indirect operation This is a great mistake

Dr Thomas Hubbard, Toledo, Ohio In the invention of instruments for bronchoscopy or esophagoscopy it is exceedingly important that they be considered from all points of view Any instrument for grasping a foreign body that will not permit easy release is a dangerous instrument A curved hook should not be used in the tracheal tract, because it is possible to so engage the curved hook in a ring of the trachea or bronchus that it is very difficult to let go A right angle hook is much safer

I want to endorse Dr Jackson's statement that, as a rule, we should use as small a tube as possible There are exceptions Peanut cases are liable to develop pneumonia, and the reason is probably the multiple fragments It is important to remove large and small fragments without a reinsertion of the tube, because of danger of subsequent laryngeal edema With the exception of cases of that character I think the small tube is preferable We should also bear in mind the liability of overlooking a foreign body which may be impacted in the ventricles of the larynx The same applies to foreign bodies in the esophagus and here the large caliber tube is particularly indicated

Dr Samuel Iglauer, Cincinnati If I understood Dr Ridpath's statement correctly, he implied that primary tuberculosis of the larynx might not be an uncommon thing That statement would have to be questioned somewhat We might not be able to demonstrate tuberculosis elsewhere than in the larynx, but the real test is the postmortem test, and I believe postmortems show that primary tuberculosis of the larynx is exceedingly rare If it were primary the prognosis would be much more hopeful As to the use of the cautery in tuberculosis of the larynx I have had occasion recently to look up the literature on this subject, and it seems to me that our prognosis should be much brighter now than ever before especially if one reads the article by Ruedi of Davos He treated over 500 patients, using chiefly the cautery according to the method of Siebenmann, which consists in destroying the entire tuberculous lesion He claims 33 per cent of cures in all his cases Some of his cases, however, have been under observation too short a time to allow for such a high percentage, but nevertheless there is no doubt that we should take a more favorable view of tuberculosis of the larynx, especially if the patient has not much pulmonary involvement The statistics of Siebenmann are better, they have covered a larger period of time, and his percentage is 16

I understood Dr Ridpath to say that he could cure papilloma of the larynx in children by fulguration I would like him to go into details as to how he carries out the treatment and how many cases he has had I have used it but once, without any apparent results He also spoke of radium You may do damage with radium I have one patient now in whom I am firmly convinced that I destroyed the papilloma, but burned the larynx to such an extent that he has a condition which is very difficult to relieve Radium was applied three times The third application produced the burn, so that great precaution should be taken in the use of radium inside the larynx I used 50 milligrams for about seven or eight hours

Dr Jackson believes in preparedness in bronchoscopy I attempted to remove a screw from an abscess in the lung It had been in situ for three years I was unable to see anything by bronchoscopy owing to the excessive amount of pus I therefore procured a giant magnet A steel rod previously shaped was introduced through the tracheotomy and the magnet applied to the rod The screw came out dangling on the end of the rod Dr Jackson also spoke of the method of seizing the point of an open safety-pin and drawing it into the tube I have done this four times Twice it was very easy because the pin was in the hypopharynx and I could remove it through the Jackson speculum But in the two other cases the pin was in the esophagus and while I seized the point of the pin and was able to withdraw it successfully, yet when it came out it opened wider and dropped back into the mouth As the pin was withdrawn the clasp of the pin caught on the cricoid cartilage As an aid to bronchoscopy in very small bronchi I have devised a little instrument, a "bronchioloscope" The object of the instrument is to give an unobstructed view by sliding a flexible forceps along the outside of the bronchioloscope

Dr H P Mosher, Boston Dr Jackson has given us the last word on the mechanical extraction of foreign bodies

Dr Ridpath works along the line I have suggested and has given us his results Primary tuberculosis of the larynx, if it is ever to be discovered by any one aside from the pathologists, is to be discovered by the man working with the lighted tube

Dr Jackson has forced a revolution in the method of anesthesia in the examination of the trachea or esophagus Dr Ridpath was not specific on this point I would like to know whether he succeeds in making his diagnosis and carrying out his repeated treatments without any anesthetic

Speaking of the movement of foreign bodies in the trachea, I was reminded of a case which puzzled me quite a bit. This was a foreign body in the esophagus This child was brought in with a history of having swallowed and retained in the esophagus a nickel when the fluoroscope showed that the nickel had not passed down, but was in the usual place at the opening of the esophagus, and had an upward and downward movement of 1 to 1 5 cm That immediately brought up the question whether I had not made a mistake and that it was in the trachea It proved, however, at operation to be in the upper part of the esophagus The explanation of the movement was that the nickel was large enough to distend the esophagus quite a bit, and, of course, as it extended it distended the anterior wall of the esophagus which is a common wall with the trachea, the movement of the trachea transmitting the foreign body to the esophagus

Dr Ross H Skillern, Philadelphia We can all do that work and we should do it When we do this bronchoscopic work we have to forget time entirely, because the sine qua non of the whole thing is thorough anesthetization of the parts That takes perhaps ten to fifteen minutes with each patient. We use a very strong solution of cocain with epinephrin, and keep on using that until the larynx and glottis are absolutely anesthetized Then introduce the laryngeal speculum and the other instruments Dr Lynch in his suspension laryngoscopy has given us one of the greatest advances that we could possibly have I think I have used nearly every model that Killian devised They were all good more or less, some of them much more satisfactory than others—they seem to improve progressively—the last model however, was not as good in my hands as were others We had trouble with our long epiglottis retractor The instrument would bend, it seemed too flimsy I got a couple of teeth one time, pulled them out of the upper jaw But on the whole, I was always more or less in a strain while the baby was being swung up Now, since Dr Lynch has perfected his instrument I go about it without any fear or trembling whatever The great advantage of his instrument is its solidness You can put it in there and you can absolutely hold up the epiglottis One must admit his instrument is more difficult to introduce than the Killian, because with the Killian we do the suspension first, whereas with his instrument you have to be able to perform a direct laryngoscopy before you can introduce this instrument properly Killian made a great stride in his discovery but it was an American who brought the instrument to its present state of perfection

Dr George F Cott, Buffalo These patients return after having the bronchoscope introduced several times, not to have the procedure repeated but because they want the effect of the cocain I know we had a few in the Killian clinic, and they came back for the cocain

Dr W E Dixon, Oklahoma City Most of these patients can be treated without any cocain at all I find it very satisfactory to pass the bronchoscope with the Jackson instrument and treat the larynx medicinally without any cocain—much easier with the Jackson speculum than with the Bruening or the Kohler

Dr George F Keiper, Lafayette, Ind We need not be in a hurry to pass the bronchoscope I remember a case in which I missed a foreign body and it was because the physician insisted that I pass the bronchoscope *without first* obtaining a roentgenogram As a rule, the patient declares he can locate the foreign body in the trachea or gullet, absolutely locate it, and yet when you have a roentgenogram made there is *sometimes no foreign* body or any evidence that there ever was a foreign body there In locating a foreign body in the eye the patient can always tell you where it is, but do you find it in this place? Not at all With reference to the treatment of asthma by the use of the bronchoscope, I have had some experience along that line and I have never failed to relieve obstinate cases which were not relieved by any other means by the use of the bronchoscope, following out the plan of Nowotny of Krakau and also as reported by Freudenthal, as well as by Secord Large of Cleveland and Henry Horn of San Francisco

Dr Robert H Good, Chicago I would like to ask if any one has tried blocking the superior laryngeal nerve with novocain for this purpose I did this the other day and it certainly worked nicely This patient made no complaint on passing the bronchoscope

Dr Lee Cohen, Baltimore I would like to place on record a case of laryngeal papilloma in a child of 5 years, who was operated on five times in fifteen months, suspension laryngoscopy being employed In spite of the most thorough removal, the use of alcohol etc, the growth recurred with monotonous regularity until after the last operation, about nine months ago Dr Burnam, an associate of Dr Howard A Kelly, was requested to use radium While the details as to dosage or the duration of each application can not be given it can be stated that the number of applications were four, and all of these were made from the outside over the larynx There has been no further sign of recurrence, nor have any contractions within the larynx occurred as has been observed repeatedly when radium applications were put inside of the larynx Furthermore, in spite of the most extensive cutting operations, involving almost every portion of the larynx, the child's voice is perfectly normal

Dr J W Murphy Cincinnati I had a case in which the stem of the tracheotomy tube which the patient had been wearing became loosened and was inspired into the left lung There were no physical signs A few hours after the accident the only pain complained of by the patient was between the shoulder blades I have also had several cases of bone foreign bodies in the esophagus and all the patient could say was that the pain was in the region of the scapula I think the internists have solved some of these problems in reference to pain in and around the stomach in which the pain is located high up near the shoulder

Dr William Redfield Butt, Canton, Ohio The point made by Dr Good in reference to anesthetization of the larynx should not be lost It is valuable Dr George Fetterolf of Philadelphia a couple of years ago, read a paper on alcohol injection of the superior laryngeal nerve for relief of pain in laryngeal tuberculosis, and it works very well in those cases The superior laryngeal nerve supplies sensation to the entire mucosa of the larynx with the exception of the tip of the epiglottis It can be injected with an ordinary hypodermic needle in the space between the hyoid and thyroid externally Combining this with a little cocain applied locally within the larynx to the tip of the epiglottis gives full anesthesia of the whole larynx

Dr Robert F Ridpath, Philadelphia I made the statement in my paper that tuberculosis of the larynx is decidedly more common than the literature indicates I also gave my reasons why we have not diagnosed it more frequently—partly due to our own inability, and partly due to it being masked or simulating other forms of infection of the larynx As my paper limited my subject to the nonoperative procedures it was necessary to have as complete a paper on that subject as possible I mentioned fulguration in papilla of the larynx In the paper I did not state that I had used it personally My statement is entirely a *quotation* Dr Harmon Smith of New York has used it quite successfully Dr Yankauer of New York also uses it Personally, I have never used it The treatment which I have instituted, *which is entirely of a medical nature*, you will find incorporated in the paper I, of course, could not speak of the surgical end in this paper

In the examination of asthmatic patients you will find it is practically an impossibility to examine these especially at the first examination, without the use of cocain You have a person who has a cough which is irritating and frequent, you have an upheaval of the whole chest, you have also the natural nervousness of the patient due to the disease All of these must be overcome Personality overcomes some obstacles, but cocain overcomes decidedly more, so we use cocain We do not use, as has been mentioned by Dr Dixon, a saturated solution of cocain and epinephrin in these cases, but we anesthetize the pharynx and the epiglottis with a 20 per cent cocain solution The trachea and bronchi can be anesthetized, if necessary This is applied with a tampon and a long applicator In my former paper I gave my methods of applying this to the trachea Patients do not come back for the effect of the cocain Any one who has had cocain applied to his throat will not come back for the second dose if he did not receive some benefit from the other medicinal agents which have been applied In fact the cocain absorbed from mucous membrane is anything but pleasing They come back because we have helped them I have shown you a tube or applicator which I devised for the application of high frequency ultra violet rays We are not at this time able to give any definite data on the subject, but we think it is an agent which all investigators should look into

Dr Chevalier Jackson, Pittsburgh One by one the various parts of the human body are being subjected, so far as possible, to examination by the eye If the bronchoscope is ever to attain the full measure of usefulness which it deserves, it will be necessary to do the bronchoscopy either under local anesthesia or without any anesthesia, general or local The internist, rightfully, will object to subjecting his patient to a general anesthetic, when the symptoms are slight, in other words, in that early stage in which a diagnostic bronchoscopy is particularly indicated This is very different from the foreign body bronchoscopy, in which the operator is perfectly justified in using any anesthetic that appeals to him as best in the particular case according to his personal equation In our clinic, Dr Patterson and I use no anesthetic at all in children under about 10 years of age, in those above this age local anesthesia is used in bronchoscopy and direct laryngoscopy We do not use general anesthesia for either bronchoscopy, esophagoscopy or laryngoscopy Dr R H Johnston tells me he gets good results from alypin anesthesia In any case requiring repetition of the procedure the danger of drug habit, as mentioned by Dr Cott, is very great, and I think all such work should be done without any anesthetic There is one point in which our experience does not coincide with that of Dr Ridpath We have never yet found it impossible to do a direct laryngoscopy or a bronchoscopy on any patient who could open his mouth Possibly our turn is yet to come Dr Hubbard's point in regard to the danger of seizing a foreign body with a snare or any other instrument which cannot be made to let go if it is necessary appeals to me as being exceedingly valuable I never had that experience but once in the early days of bronchoscopy I had a bronchoscope fastened in a bronchus by a pin being projected by cough through the holes of the bronchoscope, the point entering the opposite wall The transfixed bronchoscope could not be withdrawn until I broke the pin with forceps, taking two fragments out separately I have since modified the holes in the bronchoscope so that this accident cannot happen again Dr Hubbard's point about the peanut kernel is also excellent, but it seems to me it would apply only to peanut kernels not too large to be drawn into the distal end of the bronchoscope Larger fragments would be crushed by the forcing shut of the forcep's jaws entering the tube mouth I wish to emphasize Dr Iglauer's caution in regard to the use of radium We have not used it for anything except cancer Overdosage, especially in case of a benign growth might end in disaster I think the point made by Dr Mosher in regard to the movement of a foreign body in the esophagus is most important Dr Skillern's remarks about the time required for bronchoscopy deserve emphasis Bronchoscopy hastily done in between a hard day's work on tonsils, adenoids and other routine surgery is not conducive to the best results The experience of Dr Dixon corresponds with that of Dr Patterson and many others

Dr W R Buck, Canton, Ohio I should like to ask Dr Jackson if he has had any experience with direct laryngoscopy after thyrotomy, and other laryngeal operations

Dr Jackson Any operation on the neck is apt to create adhesions that will make direct laryngoscopy more difficult, but we have not yet encountered a case in which it could not be done We have many patients, especially children, who have had papillomas or diphtheria in whom thyrotomy or laryngostomy has previously been done In any of these cases exposure of the larynx is made easy by inserting the laryngoscope at the side of the tongue instead of over the dorsum This does away with the necessity of so much displacement External esophagotomy may render esophagoscopy exceedingly difficult, but with care and patience the esophagoscope, as well as the bronchoscope, can be introduced in any patient who can open his mouth

---

HEALTH INSURANCE AND THE MEDICAL PROFESSION

ALEXANDER LAMBERT, MD
Chairman, Committee on Social Insurance American Medical Association
NEW YORK

At the recent Conference on Social Insurance, at Washington, several medical men voiced the opinion that it would be possible to give better medical service to sick persons of moderate means and to the sick poor than is given today True, in many of the hospitals, the sick poor now receive the best that medicine can give The rich and the well-to-do can buy an equally good service But it is impossible for self-respecting people of small means who pay their bills to obtain from the profession the medical services they should have or for the profession to give them this desired grade of service under present conditions The science of medicine has grown so extensively that no one man can give everything to his patients There must be the cooperation of several men to obtain really adequate medical service today This is best perfected in the group method as seen in the team work in well organized hospitals

To obtain more effective measures of caring for the sick poor or for those of small means in a community has been the aim of the framers of the health insurance bill of the American Association for Labor Legislation Whenever compulsory health insurance has gone into operation, an amount of sickness has been disclosed that has surprised even physicians working among the poor This was especially true in England, and particularly so among the women workers In certain investigations made in this country, for example, in that in Rochester, N Y, made by the Metropolitan Life Insurance Company of New York City, it was found that only 63 8 per cent of those incapacitated for work employed physicians or were being treated in institutions, only 50 per cent of the total sick outside of institutions were in the care of physicians, and only 45 3 per cent of those sick but able to work were being cared for The State Charities Aid Association made a study in Duchess County to ascertain what percentage of those sick, in all classes of society, obtained adequate care By "adequate care" is meant that service which results in the patient's recovery when that can be expected, and which is of such a character that neither the patient nor the community incurs avoidable risks[1] It was found that, even among the well-to-do, 19 per cent did not receive adequate care. Among the middle classes — those who could pay for certain services for a certain length of time — 50 per cent. were not adequately cared for, and among the poor 68 per cent. received inadequate care. In other words, to obtain the best economic human value from employees or to give the best economic value to an employer, there must be a change in the method by which medical service can be obtained, an improvement in the service rendered, and a broadening of opportunities to render this service.

Sickness in this country is still looked on as a personal misfortune. The social conscience has not yet realized that sickness is an economic calamity for which all members of the community are responsible in varying degrees, and for which the whole community pays. It bears, of course, most hardly on the individual who suffers the calamity, but the sickness of a community reduces its economic income, since it diminishes the earning power of each individual who suffers. The greatest economic asset that a workman possesses is the health that enables him to go to work each day. If he loses that, he loses his power of earning his living. Most wage earners live on a wage from which they can store up but little to protect them against individual misfortune. The great misfortune of their poverty is not that they are poor, but that when calamity or misfortune befalls them, their poverty changes to destitution and they must suffer the destitution or turn to public charity for aid. If, then, it is possible to develop a health insurance scheme in which sickness is regarded as a calamity that may befall any one, and in which every one has joined together to sustain and aid those who are temporarily stricken, the dire effects of sickness to the family or to the individual are warded off, poverty ceases to turn into destitution, and proper convalescence is possible to the sick individual that he may regain his damaged health and be again of a value equal to his former value as an economic asset in the community. This is the justification from a social point of view for the change from the economic conditions under which we live to those which a compulsory health insurance scheme would bring about in a community.

In any health insurance scheme, intricate machinery is necessary, and physicians are an essential part of this machinery. The service rendered by the medical profession must be on a business and not on a charity basis. The public has long considered it a part of the physician's duty to give his time and knowledge to charity whenever the very poor were concerned. This has been willingly and gladly given, but because it has been so willingly given is no justification for asking that physicians under the health insurance law shall not be justly and adequately remunerated for an adequate service. Physicians must earn their livelihood in carrying out the provisions of the law, and they are justified in demanding that the standards of this livelihood shall not be lowered from the standards they already possess. These are the standards of the professional classes of the community, and not always those of the daily wage earner.

All successful measures dealing with sickness insurance require concentration of authority in local control. Hence, under the contemplated law, the fund which distributes the cash benefits and medical benefits is not a state fund or any generalized corporate carrier, but a local mutual benefit fund, the directorate of which is composed equally of employers and workmen, with a state representative. The state health insurance commission divides the state into districts, none of which shall contain less than 5,000 persons who are subject to compulsory health insurance. There shall be as many local funds in each district as shall be deemed necessary. Each fund will have special whole time referee medical officers paid by the funds, whose duty it shall be to decide when the insured shall receive the sick benefits and when the sick are well enough to go back to work. These medical officers must be paid a salary, as they are not permitted at any time to engage in private practice. They report to the health officer on the local medical committee any unhealthy conditions found or any infractions of the sanitary code or sanitary ordinances. They have the duties of a health inspector to investigate and report, and they can be removed on charges for failure to perform such duties. They are, however, paid by the funds and responsible to them, and are thus hired, by both the employers and employees to judge of the occurrence of sickness and of its limitations, and to give a general supervision during its duration.

The standards under which these medical referees are appointed are decided by the advisory medical board to the commission, one member of which is the state commissioner of health. Examinations for appointment are held either by the state civil service board or by some other adequate board. The medical referees work under regulations agreed on by the directorate of the funds and the local medical board. It is thus possible to obtain high grade men who have a grasp of preventive medicine and sanitation and also of internal medicine and surgery. This is a broader specialism than is possessed by the average physician and surgeon today.
